Notice

Hewlett-Packard to Agilent Technologies Transition

This documentation supports a product that previously shipped under the Hewlett-Packard company brand name. The brand name has now been changed to Agilent Technologies. The two products are functionally identical, only our name has changed. The document still includes references to Hewlett-Packard products, some of which have been transitioned to Agilent Technologies.
Programmer’s Guide

HP 8753D Network Analyzer
Including Option 011
Notice.

The information contained in this document is subject to change without notice.

Hewlett-Packard makes no warranty of any kind with regard to this material, including but not limited to, the implied warranties of merchantability and fitness for a particular purpose. Hewlett-Packard shall not be liable for errors contained herein or for incidental or consequential damages in connection with the furnishing, performance, or use of this material.
Warranty

This Hewlett-Packard instrument product is warranted against defects in material and workmanship for a period of one year from date of shipment. During the warranty period, Hewlett-Packard Company will, at its option, either repair or replace products which prove to be defective.

For warranty service or repair, this product must be returned to a service facility designated by Hewlett-Packard. Buyer shall prepay shipping charges to Hewlett-Packard and Hewlett-Packard shall pay shipping charges to return the product to Buyer. However, Buyer shall pay all shipping charges, duties, and taxes for products returned to Hewlett-Packard from another country.

Hewlett-Packard warrants that its software and firmware designated by Hewlett-Packard for use with an instrument will execute its programming instructions when properly installed on that instrument. Hewlett-Packard does not warrant that the operation of the instrument, or software, or firmware will be uninterrupted or error-free.

Limitation of Warranty

The foregoing warranty shall not apply to defects resulting from improper or inadequate maintenance by Buyer, Buyer-supplied software or interfacing, unauthorized modification or misuse, operation outside of the environmental specifications for the product, or improper site preparation or maintenance.

No other warranty is expressed or implied. Hewlett-Packard specifically disclaims the implied warranties of merchantability and fitness for a particular purpose.

Exclusive Remedies

The remedies provided herein are buyer’s sole and exclusive remedies. Hewlett-Packard shall not be liable for any direct, indirect, special, incidental, or consequential damages, whether based on contract, tort, or any other legal theory.
By internet, phone, or fax, get assistance with all your test and measurement needs.

**Assistance**

*Product maintenance agreements and other customer assistance agreements are available for Hewlett-Packard products. For any assistance, contact your nearest Hewlett-Packard Sales and Service Office.*

---

**Statement of Compliance**

This instrument has been designed and tested in accordance with IEC Publication 348, Safety Requirements for Electronic Measuring Apparatus, and has been supplied in a safe condition. The instruction documentation contains information and warnings which must be followed by the user to ensure safe operation and to maintain the instrument in a safe condition.

---

**Safety Notes**

The following safety notes are used throughout this manual. Familiarize yourself with each of the notes and its meaning before operating this instrument.

<table>
<thead>
<tr>
<th><strong>Warning</strong></th>
<th><strong>No operator serviceable parts inside. Refer servicing to qualified personnel. To prevent electrical shock, do not remove covers.</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning</strong></td>
<td><strong>If this instrument is used in a manner not specified by Hewlett-Packard Co., the protection provided by the instrument may be impaired.</strong></td>
</tr>
<tr>
<td><strong>Warning</strong></td>
<td><strong>For continued protection against fire hazard replace line fuse only with same type and rating (F 6.3A/250V). The use of other fuses or material is prohibited.</strong></td>
</tr>
<tr>
<td><strong>Warning</strong></td>
<td><strong>This is a Safety Class I product (provided with a protective earthing ground incorporated in the power cord). The mains plug shall only be inserted in a socket outlet provided with a protective earth contact. Any interruption of the protective conductor, inside or outside the instrument, is likely to make the instrument dangerous. Intentional interruption is prohibited.</strong></td>
</tr>
<tr>
<td><strong>Warning</strong></td>
<td><strong>If this instrument is to be energized via an external autotransformer for voltage reduction, make sure that its common terminal is connected to a neutral (earthed pole) of the power supply.</strong></td>
</tr>
<tr>
<td><strong>Warning</strong></td>
<td><strong>The power cord is connected to internal capacitors that may remain live for 10 seconds after disconnecting the plug from its power supply.</strong></td>
</tr>
</tbody>
</table>
Caution: Always use the three-prong ac power cord supplied with this instrument. Failure to ensure adequate earth grounding by not using this cord may cause instrument damage.

Caution: This instrument has autoranging line voltage input; be sure the supply voltage is within the specified range.

Caution: Ventilation Requirements: When installing the instrument in a cabinet, the convection into and out of the instrument must not be restricted. The ambient temperature (outside the cabinet) must be less than the maximum operating temperature of the instrument by 4 °C for every 100 watts dissipated in the cabinet. If the total power dissipated in the cabinet is greater than 800 watts, then forced convection must be used.

⚠️ The instruction documentation symbol. The product is marked with this symbol when it is necessary for the user to refer to the instructions in the documentation.

“CE” The CE mark is a registered trademark of the European Community. (If accompanied by a year, it is when the design was proven.)

“ISM1-A” This is a symbol of an Industrial Scientific and Medical Group 1 Class A product.

“CSA” The CSA mark is a registered trademark of the Canadian Standards Association.
How to Use This Guide

This guide uses the following conventions:

- **FRONT-PANEL KEY** This represents a key physically located on the instrument.
- **Softkey** This represents a “softkey,” a key whose label is determined by the instrument’s firmware.
- **Screen Text** This represents text displayed on the instrument’s screen.
The Installation and Quick Start Guide familiarizes you with the HP 8753D/Option 011 network analyzer's front and rear panels, electrical and environmental operating requirements, as well as procedures for installing, configuring, and verifying the operation of the analyzer.

The User's Guide shows how to make measurements, explains commonly-used features, and tells you how to get the most performance from your analyzer.

The Quick Reference Guide provides a summary of selected user features.

The Programmer's Guide provides programming information including: an HP-IB command reference, an HP-IB programming reference, as well as programming examples.

The System Verification and Test Guide provides the system verification and performance tests and the Performance Test Record for your HP 8753D/Option 011 network analyzer.

HP-IB Programming and Command Reference

This chapter is a reference for operation of the network analyzer under HP-IB control. You
should already be familiar with making measurements with the analyzer. Information about the
HP-IB commands is organized as follows:

- Analyzer Command Syntax
  - Code Naming Convention
  - Valid Characters
  - Units
  - Command Formats
- HP-IB Operation
  - Device Types
  - HP-IB Bus Structure
  - HP-IB Requirements
  - HP-IB Operational Capabilities
  - Bus Device Modes
  - Setting HP-IB Addresses
  - Response to HP-IB Meta-Messages (IEEE-488 Universal Commands)
- Analyzer Operation-Complete Commands
- Reading Analyzer Data
  - Output Queue
  - Command Query
  - Identification
  - Output Syntax
  - Marker Data
  - Array-Data Formats
  - Trace-Data Transfers
  - Stimulus-Related Values
- Data Processing Chain
  - Data Arrays
  - Fast Data Transfer Commands
  - Data Levels
  - Learn String and Calibration Kit String
Error Reporting
- Status Reporting
- The Status Byte
- The Event-Status Register and Event-Status Register B
- Error Output

Calibration

Disk File Names

Using Key Codes

Key Select Codes Arranged by Front-Panel Hardkey

HP-IB Only Commands

Alphabetical Mnemonic Listing

For information about manual operation of the analyzer, refer to the *HP 8753D Network Analyzer User’s Guide*.

---

Where to Look for More Information

Additional information covering many of the topics discussed in this chapter is located in the following:

- *Tutorial Description of the Hewlett-Packard Interface Bus*, presents a description and discussion of all aspects of the HP-IB. A thorough overview of all technical details as a broad tutorial. HP publication, HP part number 5021-1927.

- Chapter 2, “HP BASIC Programming Examples,” includes programming examples in HP BASIC.
Analyzer Command Syntax

Code Naming Convention

The analyzer HP-IB commands are derived from their front-panel key titles (where possible), according to this naming convention:

Simple commands are the first four letters of the function they control, as in POWE, the command name for power. If the function label contains two words, the first three mnemonic letters are the first three letters of the first word, and the fourth mnemonic letter is the first letter of the second word. For example, ELED is derived from electrical delay.

If there are many commands grouped together in a category, as in markers or plotting pen numbers, the command is increased to 8 letters. The first 4 letters are the category label and the last 4 letters are the function specifier. As an example, category pen numbers are represented by the command PENN, which is used in combination with several functions such as PENNDATA, PENNMEMO.

The code naming guidelines, listed in Table 1-1, are used in order to:

- make commands more meaningful and easier to remember
- maintain compatibility with other products (including the HP 8510)

Note: There are times when these guidelines are not followed due to technical considerations.

<table>
<thead>
<tr>
<th>Table 1-1. Code Naming Convention</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Convention</strong></td>
</tr>
<tr>
<td>One Word</td>
</tr>
<tr>
<td>Start</td>
</tr>
<tr>
<td>Two Words</td>
</tr>
<tr>
<td>Search Right</td>
</tr>
<tr>
<td>Two Words in a Group</td>
</tr>
<tr>
<td>Gate — Span</td>
</tr>
<tr>
<td>Three Words</td>
</tr>
<tr>
<td>Pen Num Data</td>
</tr>
</tbody>
</table>

Some codes require appendages (ON, OFF, 1, 2, etc.). Codes that do not have a front-panel equivalent are HP-IB only commands. They use a similar convention based on the common name of the function.
Valid Characters

The analyzer accepts the following ASCII characters:

- letters
- numbers
- decimal points
- +/−
- semicolons (;)
- quotation marks (”)
- carriage returns (CR)
- linefeeds (LF)

Both upper- and lower-case letters are acceptable. Carriage returns, leading zeros, spaces, and unnecessary terminators are ignored, except for those within a command or appendage. If the analyzer does not recognize a character as appropriate, it generates a syntax error message and recovers at the next terminator.

Units

The analyzer can input and output data in basic units such as Hz, dB, seconds, etc.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Name</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>Seconds</td>
<td>HZ</td>
</tr>
<tr>
<td>V</td>
<td>Volts</td>
<td>DB</td>
</tr>
</tbody>
</table>

Input data is assumed to be in basic units (see above) unless one of the following units is used (upper and lower case are equivalent):

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Name</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>MS</td>
<td>Milliseconds</td>
<td>KHZ</td>
</tr>
<tr>
<td>US</td>
<td>Microseconds</td>
<td>MHZ</td>
</tr>
<tr>
<td>NS</td>
<td>Nanoseconds</td>
<td>GHZ</td>
</tr>
<tr>
<td>PS</td>
<td>Picoseconds</td>
<td>FS</td>
</tr>
</tbody>
</table>

Command Formats

The HP-IB commands accepted by the analyzer can be grouped into five input-syntax types.

The analyzer does not distinguish between upper- and lower-case letters.

General Structure:

The general syntax structure is: [code][appendage][data][unit][terminator]

The individual sections of the syntax code are explained below.

[code]  The root mnemonic (these codes are described in the “Alphabetical Mnemonic Listing” later in this chapter.)

[appendage]  A qualifier attached to the root mnemonic. Possible appendages are ON or OFF (toggle a function ON or OFF), or integers, which specify one capability out of several. There can be no spaces or symbols between the code and the appendage.
A single operand used by the root mnemonic, usually to set the value of a function. The data can be a number or a character string. Numbers are accepted as integers or decimals, with power of ten specified by E (for example, STAR 0.2E+10; sets the start frequency to 2 GHz). Character strings must be enclosed by double quotation marks.

For example:
A title string using RMB BASIC would look like:
OUTPUT 716; "TITL""UNIT1"";
where the first two "" are an escape so that RMB BASIC will interpret the third "" properly.

The units of the operand, if applicable. If no units are specified, the analyzer assumes the basic units as described above. The data is entered into the function when either units or a terminator are received.

Indicates the end of the command, enters the data, and switches the active-entry area OFF. A semicolon (;) is the recommended terminator.

Terminators are not necessary for the analyzer to interpret commands correctly, but in the case of a syntax error, the analyzer will attempt to recover at the next terminator. The analyzer also interprets line feeds and HP-IB END OR IDENTIFY (EOI) messages as terminators.

### Syntax Types

The specific syntax types are:

**SYNTAX TYPE 1:** [code] [terminator]

These are simple action commands that require no complementary information, such as AUT0; (autoscales the active channel).

**SYNTAX TYPE 2:** [code][appendage][terminator]

These are simple action commands requiring limited customization, such as CORR0N; and CORR0FF; (error correction ON or OFF) or RECA1; RECA2; RECA3; (recall register 1, 2, 3). There can be no characters or symbols between the code and the appendage.

**Note**

In the following cases: CLEAREG[D], RECAREG[D], SAVEREG[D], and E[O][D], [D] must be 2 characters. For example, CLEAREG01; will execute, while CLEAREG1; will generate a syntax error.

**SYNTAX TYPE 3:** [code] [data] [unit][terminator]

These are data-input commands such as STAR 1.0 GHZ; (set the start frequency to 1 GHz).

**SYNTAX TYPE 4:** [code] [appendage] [data] [terminator]

These are titling and marker commands that have an appendage, such as TITR1 "STATE1" (title register 1 STATE1), TITR2 "TEST2" (title register 2 TEST2).

**QUERY SYNTAX:** [code][?]?

To query a front-panel-equivalent function, append a question mark (?) to the root mnemonic. (For example, POWE?, AVER0?, or REAL?) To query commands with integer appendages, place the question mark after the appendage.
HP-IB Operation

The Hewlett-Packard Interface Bus (HP-IB) is Hewlett-Packard's hardware, software, documentation, and support for IEEE 488.2 and IEC-625 worldwide standards for interfacing instruments. This interface allows you to operate the analyzer and peripherals in two methods:

- by an external system controller
- by the network analyzer in system-controller mode

Device Types

The HP-IB employs a party-line bus structure in which up to 15 devices can be connected on one contiguous bus. The interface consists of 16 signal lines and 8 ground lines within a shielded cable. With this cabling system, many different types of devices including instruments, computers, power meters, plotters, printers, and disk drives can be connected in parallel.

Every HP-IB device must be capable of performing one or more of the following interface functions:

Talker

A talker is a device capable of transmitting device-dependent data when addressed to talk. There can be only one active talker at any given time. Examples of this type of device include:

- power meters
- disk drives
- volt meters
- counters
- tape readers

The network analyzer is a talker when it sends trace data or marker information over the bus.

Listener

A listener is a device capable of receiving device-dependent data over the interface when addressed to listen. There can be as many as 14 listeners connected to the interface at any given time. Examples of this type of device include:

- printers
- power supplies
- signal generators

The network analyzer is a listener when it is controlled over the bus by a system controller.

Controller

A controller is defined as a device capable of:

1. managing the operation of the bus
2. addressing talkers and listeners

There can be only one active controller on the interface at any time. Examples of controllers include desktop computers, minicomputers, workstations, and the network analyzer. In a multiple-controller system, active control can be passed between controllers, but there can only be one system controller connected to the interface. The system controller acts as the master and can regain active control at any time. The analyzer is an active controller when it plots, prints, or stores to an external disk drive in the pass-control mode. The analyzer is also a system controller when it is operating in the system controller mode.
HP-IB Bus Structure

Data Bus
The data bus consists of 8 bi-directional lines that are used to transfer data from one device to another. Programming commands and data transmitted on these lines are typically encoded in ASCII, although binary encoding is often used to speed up the transfer of large arrays. Both ASCII- and binary-data formats are available to the analyzer. In addition, every byte transferred over HP-IB undergoes a handshake to insure valid data.

Handshake Lines
A three-line handshake scheme coordinates the transfer of data between talkers and listeners. To insure data integrity in multiple-listener transfers, this technique forces data transfers to occur at the transfer rate of the slowest device connected to the interface. With most computing controllers and instruments, the handshake is performed automatically, making it transparent to the programmer.

Control Lines
The data bus also has five control lines. The controller uses these lines to address devices and to send bus commands.

IFC (Interface Clear) This line is used exclusively by the system controller. When this line is true (low), all devices (whether addressed or not) unaddress and revert to an idle state.
ATN (Attention)  The active controller uses this line to define whether the information on the data bus is command-oriented or data-oriented. When this line is true (low), the bus is in the command mode, and the data lines carry bus commands. When this line is false (high), the bus is in the data mode, and the data lines carry device-dependent instructions or data.

SRQ (Service Request)  This line is set true (low) when a device requests service and the active controller services the requesting device. The network analyzer can be enabled to pull the SRQ line for a variety of reasons such as requesting control of the interface, for the purposes of printing, plotting, or accessing a disk.

REN (Remote Enable)  This line is used exclusively by the system controller. When this line is set true (low), the bus is in the remote mode, and devices are addressed by the controller to either listen or talk. When the bus is in remote mode and a device is addressed, it receives instructions from the system controller via HP-IB rather than from its front panel (pressing local returns the device to front-panel operation). When this line is set false (high), the bus and all of the connected devices return to local operation.

EOI (End or Identify)  This line is used by a talker to indicate the last data byte in a multiple-byte transmission, or by an active controller to initiate a parallel-poll sequence. The analyzer recognizes the EOI line as a terminator, and it pulls the EOI line with the last byte of a message output (data, markers, plots, prints, error messages). The analyzer does not respond to parallel poll.

**HP-IB Requirements**

Number of Interconnected Devices:  15 maximum.

Interconnection Path Maximum Cable Length:  20 meters maximum or 2 meters per device (whichever is less).

Message Transfer Scheme:  Byte serial, bit parallel asynchronous data transfer using a 3-line handshake system.

Data Rate:  Maximum of 1 megabyte-per-second over the specified distances with tri-state drivers. Actual data rate depends on the transfer rate of the slowest device connected to the bus.

Address Capability:  Primary addresses: 31 talk, 31 listen. A maximum of 1 talker and 14 listeners can be connected to the interface at given time.

Multiple-Controller Capability:  In systems with more than one controller (such as this instrument), only one controller can be active at any given time. The active controller can pass control to another controller, but only the system controller can assume unconditional control. Only one system controller is allowed.
**HP-IB Operational Capabilities**

On the network analyzer's rear panel, next to the HP-IB connector, there is a list of HP-IB device subsets as defined by the IEEE 488.2 standard. The analyzer has the following capabilities:

- **SH1** Full-source handshake.
- **AH1** Full-acceptor handshake.
- **T6** Basic talker, answers serial poll, unaddresses if MLA is issued. No talk-only mode.
- **L4** Basic listener, unaddresses if MTA is issued. No listen-only mode.
- **SR1** Complete service request (SRQ) capabilities.
- **RL1** Complete remote/local capability including local lockout.
- **PP0** Does not respond to parallel poll.
- **DC1** Complete device clear.
- **DT1** Responds to a Group Execute Trigger (GET) in the hold-trigger mode.
- **C1,C2,C3** System controller capabilities in system-controller mode.
- **C10** Pass control capabilities in pass-control mode.
- **E2** Tri-state drivers.
- **LE0** No extended listener capabilities.
- **TE0** No extended talker capabilities.

These codes are completely explained in the IEEE Std 488 documents, published by the Institute of Electrical and Electronic Engineers, Inc., 345 East 47th Street, New York, New York 11017.
HP-IB Status Indicators

When the analyzer is connected to other instruments over the HP-IB, the HP-IB status indicators illuminate to display the current status of the analyzer. The HP-IB status indicators are located in the instrument-state function block on the front panel of the network analyzer.

R = Remote Operation
L = Listen mode
T = Talk mode
S = Service request (SRQ) asserted by the analyzer

Bus Device Modes

The analyzer uses a single-bus architecture. The single bus allows both the analyzer and the host controller to have complete access to the peripherals in the system.

Three different controller modes are possible in an HP-IB system:

- system-controller mode
- talker/listener mode
- pass-control mode

Figure 1-2. Analyzer Single Bus Concept
System-Controller Mode
This mode allows the analyzer to control peripherals directly in a stand-alone environment (without an external controller). This mode can only be selected manually from the analyzer's front panel. It can only be used if no active computer or instrument controller is connected to the system via HP-IB. If an attempt is made to set the network analyzer to the system-controller mode when another controller is connected to the interface, the following message is displayed on the analyzer's display screen:
"ANOTHER SYSTEM CONTROLLER ON HP-IB BUS"
The analyzer must be set to the system-controller mode in order to access peripherals from the front panel. In this mode, the analyzer can directly control peripherals (plotters, printers, disk drives, power meters, etc.) and the analyzer may plot, print, store on disk or perform power meter functions.

Note  Do not attempt to use this mode for programming. HP recommends using an external instrument controller when programming. See the following section, "Talker/Listener Mode."

Talker/Listener Mode
This is the mode that is normally used for remote programming of the analyzer. In talker/listener mode, the analyzer and all peripheral devices are controlled from an external instrument controller. The controller can command the analyzer to talk and other devices to listen. The analyzer and peripheral devices cannot talk directly to each other unless the computer sets up a data path between them. This mode allows the analyzer to act as either a talker or a listener, as required by the controlling computer for the particular operation in progress.

Pass-Control Mode
This mode allows the computer to control the analyzer via HP-IB (as with the talker/listener mode), but also allows the analyzer to take control of the interface in order to plot, print, or access a disk. During an analyzer-controlled peripheral operation, the host computer is free to perform other internal tasks (i.e. data or display manipulation) while the analyzer is controlling the bus. After the analyzer-controlled task is completed, the analyzer returns control to the system controller.

Note  Performing an instrument preset does not affect the selected bus mode, although the bus mode will return to talker/listener mode if the line power is cycled.

Note  "Specifications and Measurement Uncertainties" in the HP 8753D Network Analyzer User's Guide provides information on setting the correct bus mode from the front-panel menu.

Analyzer Bus Modes
As discussed earlier, under HP-IB control, the analyzer can operate in one of three modes: talker/listener, pass-control, or system-controller mode.

In talker/listener mode, the analyzer behaves as a simple device on the bus. While in this mode, the analyzer can make a plot or print using the OUTPLOT; or OUTPRIN; commands. The analyzer will wait until it is addresses to talk by the system controller and then dump the display to a plotter/printer that the system controller has addressed to listen. Use of the commands PLCT; and PRINALL; require control to be passed to another controller.
In pass-control mode, the analyzer can request control from the system controller and take control of the bus if the controller addresses it to take control. This allows the analyzer to take control of printers, plotters, and disk drives on an as-needed basis. The analyzer sets event-status register bit 1 when it needs control of the interface, and the analyzer will transfer control back to the system controller at the completion of the operation. It will pass control back to its controller address, specified by ADDRCONT.

The analyzer can also operate in the system-controller mode. This mode is only used when there is no remote controller on the bus. In this mode, the analyzer takes control of the bus, and uses it whenever it needs to access a peripheral. While the analyzer is in this mode, no other devices on the bus can attempt to take control. Specifically, the REN, ATN, and IFC lines must remain unasserted, and the data lines must be freed by all but the addressed talker.

**Setting HP-IB Addresses**

In systems interfaced using HP-IB, each instrument on the bus is identified by an HP-IB address. This address code must be different for each instrument on the bus. These addresses are stored in short-term, non-volatile memory and are not affected when you press (Present) or cycle the power. The analyzer occupies two HP-IB addresses: the instrument itself and the display. The display address is derived from the instrument address by complementing the instrument’s least-significant bit. Hence, if the instrument is at an even address, the display occupies the next higher address. If the instrument is at an odd address, the display occupies the next lower address.

The analyzer addresses are set by pressing (local) SET ADDRESSES. In system-controller mode, the addresses must be set for the plotter, printer, disk drive, and power meter.

The default address for the analyzer is device 16, and the display address is device 17.

| Note | There is also an address for the system controller. This address refers to the controller when the network analyzer is being used in pass-control mode. This is the address that control is passed back to when the analyzer-controlled operation is complete. |

**Response to HP-IB Meta-Messages (IEEE-488 Universal Commands)**

**Abort**

The analyzer responds to the abort message (IFC) by halting all listener,talker, and controller functions.

**Device Clear**

The analyzer responds to the device clear commands (DCL, SDC) by clearing the input and output queues, and clearing any HP-IB errors. The status registers and the error queue are unaffected.

**Local**

The analyzer will go into local mode if the local command (GTL) is received, the remote line is unasserted, or the front-panel local key is pressed. Changing the analyzer’s HP-IB status from remote to local does not affect any of the front-panel functions or values.
Local Lockout

If the analyzer receives the local-lockout command (LLO) while it is in remote mode, it will disable the entire front panel except for the line power switch. A local-lockout condition can only be cleared by releasing the remote line, although the local command (GTL) will place the instrument temporarily in local mode.

Parallel Poll

The analyzer does not respond to parallel-poll configure (PPC) or parallel-poll unconfigure (PPU) messages.

Pass Control

If the analyzer is in pass-control mode, is addressed to talk, and receives the take-control command (TCT), from the system control it will take active control of the bus. If the analyzer is not requesting control, it will immediately pass control to the system controller's address. Otherwise, the analyzer will execute the function for which it sought control of the bus and then pass control back to the system controller.

Remote

The analyzer will go into remote mode when the remote line is asserted and the analyzer is addressed to listen. While the analyzer is held in remote mode, all front-panel keys (with the exception of local) are disabled. Changing the analyzer’s HP-IB status from remote to local does not affect any front-panel settings or values.

Serial Poll

The analyzer will respond to a serial poll with its status byte, as defined in the “Status Reporting” section of this chapter. To initiate the serial-poll sequence, address the analyzer to talk and issue a serial-poll enable command (SPE). Upon receiving this command, the analyzer will return its status byte. End the sequence by issuing a serial-poll disable command (SPD). A serial poll does not affect the value of the status byte, and it does not set the instrument to remote mode.

Trigger

In hold mode, the analyzer responds to device trigger by taking a single sweep. The analyzer responds only to selected-device trigger (SDT). This means that it will not respond to group execute-trigger (GET) unless it is addressed to listen. The analyzer will not respond to GET if it is not in hold mode.
Analyzer Operation

Operation Complete

Occasionally, there is a need to know when certain analyzer operations have been completed. There is an operation-complete function (OPC) that allows a synchronization of programs with the execution of certain key commands. This mechanism is activated by issuing OPC; or OPC?, prior to an OPC-compatible command. The status byte or ESR operation-complete bit will then be set after the execution of the OPC-compatible command. For example, issuing OPC; SING; causes the OPC bit to be set when the single sweep is finished. Issuing OPC?; in place of the OPC; causes the analyzer to output a one (1) when the command execution is complete. The analyzer will halt the computer by not transmitting the one (1) until the command has completed. For example, executing OPC?; PRES;, and then immediately querying the analyzer causes the bus to halt until the instrument preset is complete and the analyzer outputs a one (1).

As another example, consider the timing of sweep completion. Send the command string SMET 3 S;OPC?;SING; to the analyzer. This string sets the analyzer sweep time to 3 seconds, and then waits for completion of a single sweep to respond with a one (1). The computer should be programmed to read the number one (1) response from the analyzer indicating completion of the single sweep. At this point a valid trace exists and the trace data could be read into the computer.

Reading Analyzer Data

Output Queue
Whenever an output-data command is received, the analyzer puts the data into the output queue (or buffer) where it is held until the system controller outputs the next read command. The queue, however, is only one event long: the next output-data command will overwrite the data already in the queue. Therefore, it is important to read the output queue immediately after every query or data request from the analyzer.

Command Query
All instrument functions can be queried to find the current ON/OFF state or value. For instrument state commands, append the question mark character (?) to the command to query the state of the functions. Suppose the operator has changed the power level from the analyzer’s front panel. The computer can ascertain the new power level using the analyzer’s command-query function. If a question mark is appended to the root of a command, the analyzer will output the value of that function. For instance, \texttt{POWE 7 DB}; sets the source power to 7 dB, and \texttt{POWE?}; outputs the current RF source power at the test port. When the analyzer receives \texttt{POWE?};, it prepares to transmit the current RF source power level. This condition illuminates the analyzer front-panel talk light (T). In this case, the analyzer transmits the output power to the controller.

ON/OFF commands can be also be queried. The reply is a one (1) if the function is ON or a zero (0) if it is OFF. For example, if a command controls an active function that is underlined on the analyzer display, querying that command yields a one (1) if the command is underlined or a zero (0) if it is not. As another example, there are nine options on the format menu and only one option is underlined at a time. Only the underlined option will return a one when queried.

For instance, send the command string \texttt{DUAC?}; to the analyzer. If dual-channel display is switched ON, the analyzer will return a one (1) to the instrument controller.

Similarly, to determine if phase is being measured and displayed, send the command string \texttt{PHAS?}; to the analyzer. In this case, the analyzer will return a one (1) if phase is currently being displayed. Since the command only applies to the active channel, the response to the \texttt{PHAS?}; query depends on which channel is active.

Identification
The analyzer’s response to \texttt{IDN?}; is \texttt{HEWLETT PACKARD,87NND,0,X.XX} where \texttt{87NND} is the model number of the instrument and \texttt{X.XX} is the firmware revision of the instrument.

The analyzer also has the capability to output its serial number with the command \texttt{OUTPSERN}; and to output its installed options with the command \texttt{OUTPOPTS};.

Output Syntax
The following three types of data are transmitted by the analyzer in ASCII format:
- response to query
- certain output commands
- ASCII floating-point (FORM 4) array transfers
Marker-output commands and queried commands are output in ASCII format only, meaning that each character and each digit is transmitted as a separate byte, leaving the receiving computer to reconstruct the numbers and strings. Numbers are transmitted as 24-character strings, consisting of:

![Figure 1-3. FORM 4 (ASCII) Data-Transfer Character String](image)

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign</td>
<td>'-' for negative, blank for positive.</td>
</tr>
<tr>

<td>Exponent notation.</td>
</tr>
<tr>
<td>Sign</td>
<td>'-' for negative, '+' for positive.</td>
</tr>
<tr>
<td>Exponent</td>
<td>Two digits for the exponent.</td>
</tr>
</tbody>
</table>

When multiple numbers are sent, the numbers are separated by commas. When number pairs are sent, the numbers are separated by a comma and terminated with a line feed (LF).

**Marker data**

The network analyzer offers several options for outputting trace-related data. Trace information can be read out of the analyzer in several methods. Data can be selectively read from the trace using the markers, or the entire trace can be read by the controller. If only specific information is required (such as a single point on the trace or the result of a marker search), the marker output command can be used to read the information. Specific data points can be read using the OUTPDATP or OUTPDATR commands. These commands allow a much faster data transfer than when using markers to output specific data points. For more information on these commands, see “Limit Line and Data Point Special Functions,” located in Chapter 2.

To read the trace data using the marker, the marker must first be assigned to the desired frequency. This is accomplished using the marker commands. The controller sends a marker command followed by a frequency within the trace-data range. If the actual desired frequency was not sampled, the markers can be set to continuous mode and the desired marker value will be linearly interpolated from the two nearest points. This interpolation can be prevented by putting the markers into discrete mode. Discrete mode allows the marker to only be positioned on a measured trace-data point.

As an alternative, the analyzer can be programmed to choose the stimulus value by using the MARKER SEARCH function. Maximum, minimum, target value, or bandwidths search can be automatically determined with MARKER SEARCH. To continually update the search, switch the marker tracking ON. The trace-maximum search will remain activated until:

- The search is switched OFF.
- The tracking is switched OFF.
All markers are switched OFF.

Marker data can be output to a controller with a command to the analyzer. This set of commands causes the analyzer to transmit three numbers: marker value 1, marker value 2, and marker stimulus value. For example, in log-magnitude display mode we get the log magnitude at the marker (value 1), zero (for value 2), and the marker frequency. See Table 1-3 for a complete listing of all the possibilities for values 1 and 2. The three possibilities for the marker stimulus value are:

- frequency
- time (as in time domain, Option 010 Only)
- CW time
- power (in power sweep mode)

*The marker readout values are the marker values displayed in the upper right-hand corner of the display. They also correspond to the value and auxiliary value associated with the fixed marker.

†Value 2 is not significant in this format, though it is included in data transfers. See also OUTPFOR.

### Array-Data Formats

The analyzer can transmit and receive arrays in the analyzer’s internal binary format as well as four different numeric formats. The current format is set with the FORM1, FORM2, FORM3, FORM4, and FORM5 commands. These commands do not affect learn-string transfers, calibration-kit string transfers, or non-array transfers, such as command query, or output marker values.

A transmitted array will be output in the current format, and the analyzer will attempt to read incoming arrays according to the current format. Each data point in an array is a pair of
numbers, usually a real/imaginary pair. The number of data points in each array is the same as the number of points in the current sweep.

The five formats are described below:

**FORM1**

The analyzer's internal binary format, 6 bytes-per-data point. The array is preceded by a four-byte header. The first two bytes represent the string "#A", the standard block header. The second two bytes are an integer representing the number of bytes in the block to follow. FORM 1 is best applied when rapid data transfers, not to be modified by the computer nor interpreted by the user, are required.

**FORM2**

IEEE 32-bit floating-point format, 8 bytes-per-data point. The data is preceded by the same header as in FORM1. Each number consists of a 1-bit sign, an 8-bit biased exponent, and a 23-bit mantissa. FORM 2 is the format of choice if your computer supports single-precision floating-point numbers.

**FORM3**

IEEE 64-bit floating-point format, 16 bytes-per-data point. The data is preceded by the same header as in FORM 1. Each number consists of a 1-bit sign, an 11-bit biased exponent, and a 52-bit mantissa. This format may be used with double-precision floating-point numbers. No additional precision is available in the analyzer data, but FORM 3 may be a convenient form for transferring data to your computer.

**FORM4**

ASCII floating-point format. The data is transmitted as ASCII numbers, as described in "Output Syntax".

There is no header. The analyzer always uses FORM 4 to transfer data that is not related to array transfers (i.e. marker responses and instrument settings).

**FORM5**

PC-DOS 32-bit floating-point format with 4 bytes-per-number, 8 bytes-per-data point. The data is preceded by the same header as in FORM 1. The byte order is reversed to comply with PC-DOS formats. If you are using a PC-based controller, FORM 5 is the most effective format to use.

The analyzer terminates each transmission by asserting the EOI interface line with the last byte transmitted. Table 1-4 offers a comparative overview of the five array-data formats.

Trace-Data Transfers

Transferring trace-data from the analyzer using an instrument controller can be divided into three steps:

1. allocating an array to receive and store the data
2. commanding the analyzer to transmit the data
3. accepting the transferred data

Data residing in the analyzer is always stored in pairs for each data point (to accommodate real/imaginary pairs). Hence, the receiving array has to be two elements wide, and as deep as the number of points in the array being transferred. Memory space for the array must be declared before any data can be transferred from the analyzer to the computer.

As mentioned earlier, the analyzer can transmit data over HP-IB in five different formats. The type of format affects what kind of data array is declared (real or integer), because the format determines what type of data is transferred. Examples of data transfers using different formats are discussed “Example 3: Measurement Data Transfer.” For information on the various types of data that can be obtained (raw data, error-corrected data, etc.), see “Data Levels,” located later in this chapter.

For information on transferring trace-data by selected points, see “Limit Line and Data Point Special Functions,” located in Chapter 2.

Note  "Example 7C: Reading ASCII Disk Files to the Instrument Controller's Disk File," located in Chapter 2, explains how to access disk files from a computer.
Stimulus-Related Values

Frequency-related values are calculated for the analyzer display. The start and stop frequencies or center and span frequencies of the selected frequency range are available to the programmer.

In a linear frequency range, the frequency values can be easily calculated because the trace data points are equally spaced across the trace. Relating the data from a linear frequency sweep to frequency can be done by querying the start frequency, the frequency span, and the number of points in the trace.

Given that information, the frequency of point \( n \) in a linear-frequency sweep is represented by the equation:

\[ F = \text{Start frequency} + (n-1) \times \text{Span} / (\text{Points}-1) \]

In most cases, this is an easy solution for determining the related frequency value that corresponds with a data point. This technique is illustrated in "Example 3B: Data Transfer Using FORM 4 (ASCII Format)."

When using log sweep or a list-frequency sweep, the points are not evenly spaced over the frequency range of the sweep. In these cases, an effective way of determining the frequencies of the current sweep is to use the OUTPLML command. Although this command is normally used for limit lines, it can also be used to identify all of the frequency points in a sweep. Limit lines do not need to be on in order to read the frequencies directly out of the instrument with the OUTPLML command. Refer to example 3D, "Data Transfer Using Frequency Array Information."

Note
Another method of identifying all of the frequency points in a sweep is to use the marker commands MARKBUCKx and OUTPMARK in a FOR NEXT programming loop that corresponds to the number of points in the sweep. MARKBUCKx places a marker at a point in the sweep, where \( x \) is the number of the point in a sweep, and OUTPMARK outputs the stimulus value as part of the marker data.
Data-Processing Chain

This section describes the manner in which the analyzer processes measurement data. It includes information on data arrays, common output commands, data levels, the learn string, and the calibration kit string.

Data Arrays

Figure 1-4 shows the different kinds of data available within the instrument:

- pre-rung measured data
- raw measured data
- error-corrected data
- formatted data
- trace memory
- calibration coefficients

Trace memory can be directly output to a controller with OUTMEMO; but it cannot be directly transmitted back.
Figure 1-4. The Data-Processing Chain For Measurement Outputs

All the data-output commands are designed to ensure that the data transmitted reflects the current state of the instrument:

- OUTPDATA, OUTPRAW<1>, OUTPFORM, OUTPDATE, OUTPRAF<1> and OUTPFORF will not transmit data until all formatting functions have completed.
- OUTPPRE transmits data in conjunction with Take4 mode and the SWPSTART command. See Programming Example 2E: Take4 — Error Correction Processed on an External PC.
- OUTPLIML, OUTPLIMM, and OUTPLIMF will not transmit data until the limit test has occurred (if activated).
- **OUTPMARK** will activate a marker if a marker is not already selected. It will also insure that any current marker searches have been completed before transmitting data.

- **OUTPMSTA** insures that the statistics have been calculated for the current trace before transmitting data. If the statistics are not activated, it will activate the statistics long enough to update the current values before deactivating the statistics.

- **OUTPMWID** insures that a bandwidth search has been executed for the current trace before transmitting data. If the bandwidth-search function is not activated, it will activate the bandwidth-search function long enough to update the current values before switching off the bandwidth-search functions.

**Fast Data Transfer Commands**

The HP 8753D has four distinct fast data transfer commands. These commands circumvent the internal “byte handler” routine and output trace dumps as block data. In other words, the analyzer outputs the entire array without allowing any process swapping to occur. FORM4, ASCII data transfer times are not affected by these routines. However, there are speed improvements with binary data formats. The following is a description of the four fast data transfer commands:

- **OUTPDATF** outputs the error corrected data from the active channel in the current output format. This data may be input to the analyzer using the INPDATA command.

- **OUTPFORF** outputs the formatted display trace array from the active channel in the current output format, but only the first number in each of the OUTPFORM data pairs is actually transferred for the display formats LOG MAG, PHASE, group DELAY, LIN MAG, SWR, REAL and IMAGinary. Because the data array does not contain the second value for these display formats, the INPUFORM command may not be used to re-input the data back into the analyzer. The second value may not be significant in some display formats (see Table 1-4), thus eliminating it reduces the number of bytes transferred.

- **OUTPMEMF** outputs the memory trace from the active channel. The data is in real/imaginary pairs, and, as such, may be input back into the memory trace using INPDATA or INPUFORM followed by the DATI command.

- **OUTPRAFl>** outputs the raw measurement data trace. The data may be input back into the memory trace using the INPURAW<1> command.

**Data Levels**

Different levels of data can be read out of the instrument. Refer to the data-processing chain in Figure 1-4. The following list describes the different types of data that are available from the network analyzer.

- **Pre-raw data**
  
  This is the raw data without sampler correction or attenuator offsets applied. With raw offsets turned off, the calibration coefficients generated can be transferred to an external controller and used with the data gathered using the OUTPPRE[1-4] commands. See Programming Example 2E: Take 4 — Error Correction Processed on an External Computer. The four arrays refer to S11, S21, S12 and S22 respectively. These four arrays are available only if 2-port correction or Take 4 mode is on. This data is represented in real/imaginary pairs.

- **Raw data**
  
  The basic measurement data, reflecting the stimulus parameters, IF averaging, and IF bandwidth. If a full 2-port measurement calibration is activated, there are actually four
raw arrays kept: one for each raw S-parameter. The data can be output to a controller with the commands OUTPRAW1, OUTPRAW2, OUTPRAW3, OUTPRAW4. Normally, only raw 1 is available, and it holds the current parameter. If a 2-port measurement calibration is active, the four arrays refer to S11, S21, S12, and S22 respectively. This data is represented in real/imaginary pairs.

Error-corrected data

This is the raw data with error-correction applied. The array represents the currently measured parameter, and is stored in real/imaginary pairs. The error-corrected data can be output to a controller with the OUTPDATA; command. The OUTPMemo; command reads the trace memory, if available. The trace memory also contains error-corrected data. Note that neither raw nor error-corrected data reflect such post-processing functions as electrical-delay offset, trace math, or time-domain gating.

Formatted data

This is the array of data actually being displayed. It reflects all post-processing functions such as electrical delay and time domain. The units of the array output depend on the current display format. See Table 1-3 for the various units defined as a function of display format.

Calibration coefficients

The results of a measurement calibration are arrays containing calibration coefficients. These calibration coefficients are then used in the error-correction routines. Each array corresponds to a specific error term in the error model. The HP 8753D Network Analyzer User's Manual details which error coefficients are used for specific calibration types, as well as the arrays those coefficients can be found in. Not all calibration types use all 12 arrays. The data is stored as real/imaginary pairs.

Generally, formatted data is the most useful of the five data levels, because it is the same information the operator sees on the display. However if post-processing is unnecessary (e.g. possibly in cases involving smoothing), error-corrected data may be more desirable. Error-corrected data also affords the user the opportunity to input the data to the network analyzer and apply post-processing at another time.

Learn String and Calibration-Kit String

The learn string is a summary of the instrument state. It includes all the front-panel settings, the limit-test tables, and the list-frequency table for the current instrument state. It does not include calibration data or the information stored in the save/recall registers.

The learn string can be output to a controller with the OUTPLEAS; command, which commands the analyzer to start transmitting the binary string. The string has a fixed length for a given firmware revision. The array has the same header as in FORM 1. See Example 5, “Using the Learn String.”

The calibration kit includes a set of key characteristics of the calibration standards used to determine the calibration accuracy. There are default kits for several different connector types. There is also space for a user-defined calibration kit. The command OUTPCALK outputs the currently active calibration kit as a binary string in FORM 1. As with the learn string, the calibration-kit string has a fixed length for a given firmware revision.
Error Reporting

This section describes the analyzer's error-reporting process. It includes information on status reporting, the status byte, the event-status registers, and the error output.

Status Reporting

The analyzer status reporting structure is depicted in Figure 1-5. Refer to Table 1-5 for a description of each bit within the status reporting structure.

</tbody>
</table>
The Status Byte

The analyzer has a status-reporting mechanism that reports information about specific analyzer functions and events. The status byte (consisting of summary bits) is the top-level register. Each bit reflects the condition of another register or queue. If a summary bit is set (equals 1), the corresponding register or queue should be read to obtain the status information and clear the condition. Reading the status byte does not affect the state of the summary bits. The summary bits always reflect the condition of the summarized queue or register. The status byte can be read by a serial poll or by using the command OUTPSTAT. When using this command, the sequencing bit can be set by the operator during the execution of a test sequence. OUTPSTAT does not automatically put the instrument in remote mode, thus giving the operator access to the analyzer front-panel functions.

The status byte:

- summarizes the error queue
- summarizes two event-status registers that monitor specific conditions inside the instrument
- contains a bit that is set when the instrument is issuing a service request (SRQ) over HP-IB
- contains a bit that is set when the analyzer has data to transmit over HP-IB

Any bit in the status byte can be selectively enabled to generate a service request (SRQ) when set. Setting a bit in the service-request-enable register with the SRE\textsuperscript{nn} command enables the corresponding bit in the status byte. The units variable \textit{nn} represents the binary equivalent of the bit in the status byte. For example, SRE24; enables status-byte bits 3 and 4 (since $2^3 + 2^4 = 24$) and disables all the other bits. SRE will not affect the state of the status-register bits.

The status byte also summarizes two queues: the output queue and the error queue. (The error queue is described in the next section.) When the analyzer outputs information, it puts the information in the output queue where it resides until the controller reads it. The output queue is only one event long. Therefore, the next output request will clear the current data. The summary bit is set whenever there is data in the output queue.

The Event-Status Register and Event-Status Register B

The event-status register and event-status register B are the other two registers in the status-reporting structure. They are selectively summarized by bits in the status byte via enable registers. The event-status registers consist of latched bits. A latched bit is set at the beginning of a specific trigger condition in the instrument. It can only be cleared by reading the register. The bit will not be reactivated until the condition occurs again. If a bit in one of these two registers is enabled, it is summarized by the summary bit in the status byte. The registers are enabled using the commands ESE\textsuperscript{nn}; and ESN\textsuperscript{nn};, both of which work in the same manner as SRE\textsuperscript{nn}. The units variable \textit{nn} represents the binary equivalent of the bit in the status byte.

If a bit in one of the event-status registers is enabled, and therefore, the summary bit in the status byte is enabled, an SRQ will be generated. The SRQ will not be cleared until one of the five following conditions expire:

1. The event-status register is read, clearing the latched bit.
2. The summary bit in the status byte is disabled.
3. The event-status register bit is disabled.
4. The status registers are cleared with the CLES; command.
5. An instrument preset is performed.
Service requests generated when there are error messages or when the instrument is waiting for the Group Execute Trigger (GET) command are cleared by:

- reading the errors
- issuing GET (disabling the bits)
- clearing the status registers

Error Output

When an error condition is detected in the analyzer, a message is generated, displayed on the analyzer's display screen, and placed in the error queue. Error messages consist of an error number followed by an ASCII string no more than 50-characters long. The string contains the same message that appears on the analyzer's display. The error queue holds up to 20 error messages in the order in which they occur. The error messages remain in the error queue until the errors are read by the system controller using the command OUTPERRO. The OUTPERRO command outputs one error message.

Note

The error queue can only be cleared by performing an instrument preset or by cycling the line power. In order to keep the queue up-to-date, it is important to read all of the messages out of the queue each time errors are detected.

Calibration

Measurement calibration over HP-IB follows the same command sequence as a calibration from the front-panel. For detailed information, refer to “Optimizing Measurement Results” in the HP 8753D Network Analyzer User's Guide.

1. Start by selecting a calibration kit, such as 50 ohm type N (CALN50;).
2. Select a calibration type, such as S11 1-port (CALIS1111;).
3. Call each class used by the calibration type, such as FORWARD; OPEN (CLASS1;). During a 2-port calibration, the reflection, transmission, and isolation subfaces must be opened before the classes in the subsequence are called, and then closed at the end of each subsequence.
4. If a class has more than one standard in it, select a standard from the menu presented (STANA to STANG).
5. If, during a calibration, two standards are measured to satisfy one class, the class must be closed with DONE;.
6. Declare the calibration done, such as with DONE 1-PORT CAL (SAV1; over HP-IB).

The STANA to STANG commands will hold off the HP-IB until completion because they trigger a sweep. If a class has only one standard in it, which means that it will trigger a sweep when called, the class command will also hold off the HP-IB.

Note

Since different cal kits can have a different number of standards in a given class, any automated calibration sequence is valid only for a specific cal kit.

1 One path, 2-port cad duplicates arrays 1 to 6 in arrays 7 to 12.

2 Response and isolation corrects for crosstalk and transmission tracking in transmission measurements, and for directivity and reflection tracking in reflection measurements.

**Meaning of first subscript:**
- D = directivity
- S = source match
- R = reflection tracking
- X = crosstalk or isolation
- L = load match
- T = transmission tracking

**Meaning of second subscript:**
- F = forward
- R = reverse
Disk File Names

Disk files created by the analyzer consist of a state name of up to eight characters, such as FILTER, appended with up to two characters. In LIF format, the file name is FILTERXX. In DOS format, the filename is FILTER.XX. The first appended character is the file type, telling the kind of information in the file. The second appended character is a data index, used to distinguish files of the same type.

Error corrected data, raw data, formatted data, memory traces, and calibration files are FORM 3 data files (IEEE 64-bit floating point format). The other files are not meant to be decoded. Table 1-8 lists the appended characters and their meanings.

Using Key Codes

Using key codes allows remote control of the analyzer keys and can be used as an alternative to using other HP-IB commands. This may be useful, but it is a highly recommended programming practice to use the HP-IB command mnemonic appropriate for the function desired.

![Diagram of key codes]

**Figure 1-6. Key Codes**

When using key codes, the following notes must be taken into consideration:

**Note 1:** An "invalid key" is reported with a 63.

**Note 2:** `OUTPKEY`; outputs the key code of the last key pressed. This command reports a knob turn as a -1.

**Note 3:** `KOR?`; outputs the last key code or knob count. If the reply is positive, it is a key code. If it is negative, then set bit 15 equal to bit 14, and the resulting two byte integer is the RPG knob count. It can be either positive or negative. There are about 120 counts per turn.
Key Select Codes Arranged by Front-Panel Hardkey

The HP-IB mnemonics in the following table are functionally arranged by their front-panel key equivalent. For example, all of the mnemonics that correspond to softkeys accessed by means of the (cal) key, will be listed under the (cal) key in the following table.

Keys
- AVG
- CAL-Error correction, calibration
- CAL-Calibration kits
- CAL-Power Meter Calibration
- CHANNEL
- COPY
- DISPLAY
- ENTRY
- FORMAT
- LOCAL
- MEAS
- MENU (stimulus)
- MARKER
- MARKER FCTN
- SAVE/RECALL-Internal registers
- SAVE/RECALL-Disk files
- SCALE REF
- SEQ-Sequencing
- STIMULUS
- SYSTEM
- SYSTEM-Limit testing
- SYSTEM-Transform

Column headings:

Function The front-panel function affected by the mnemonic.
Action The effects of the mnemonic on that function.
Mnemonic The HP-IB mnemonic.
S Syntax type. See “Syntax Types,” earlier in this chapter.
? Interrogate response. If a response is defined, it is listed.
O OPC-compatible command.
Range The range of acceptable inputs and corresponding units.

Symbol conventions:

[ ] Optional data.
D Numerical data.
I An integer appendage that is part of the command. For example, CLEA<>I>, where I= 1 to 5, indicates that the actual commands are CLEA1, CLEA2, CLEA3, CLEA4, and CLEA5.
$ A character string operand which must be enclosed by double quotes.
< > A necessary appendage.
| An either/or choice in appendages.

†† The class commands are OPC-compatible if there is only one standard in the class. If there is just one standard, that standard is measured automatically. If there is more than one standard in the class, the class command only calls another menu.

† For frequency or power sweeps, refer to Chapter 12, "Preset State and Memory Allocation," in the HP 8753D User's Guide. For CW time: 0 to 24 hours. For frequency sweep, transform on: ±1 frequency step. For CW time sweep, transform on: ±1 time step.

# For log mag: ± 500 dB. For phase: ± 500 degrees. For Smith chart and Polar: ± 500 units. For linear magnitude: ± 500 units. For SWR: ± 500 units. The scale is always positive, and has minimum values of .001 dB, 10e-12 degrees, 10e-15 seconds, and 10 picounits.

<table>
<thead>
<tr>
<th>Action</th>
<th>Mnemonic</th>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identify instrument</td>
<td>IDN?</td>
<td>1</td>
<td>Outputs the identification string &quot;HEWLETT PACKARD, 87 N N D, 0, X X X&quot;, where 87 N N D is the model number of the instrument and X X X is the firmware revision of the instrument.</td>
</tr>
<tr>
<td>Key</td>
<td>KEY[D]</td>
<td>1</td>
<td>D Imitates pressing a key. The data transmitted is the key code, as defined in Figure 1-6. Range for D = 1 to 61.</td>
</tr>
<tr>
<td>Key code</td>
<td>KOR?</td>
<td>1</td>
<td>Outputs last key code or knob count. If the reply is positive, it is a key code. If it is negative, then set bit 15 equal to bit 14, and the resulting two byte integer is the FPGA knob count. It can be either positive or negative. There are about 120 counts per turn.</td>
</tr>
<tr>
<td>Move marker</td>
<td>MARKBUCK[D]</td>
<td>2</td>
<td>D Moves the marker to the selected point on the trace. On a 201 point sweep, D can range from 0 to 200.</td>
</tr>
<tr>
<td>On completion</td>
<td>OPC</td>
<td>1</td>
<td>Causes reporting of the last OPC-compatible command completion.</td>
</tr>
<tr>
<td>Plot/print softkeys</td>
<td>PSOF&lt;ON</td>
<td>OFF&gt;</td>
<td>2</td>
</tr>
<tr>
<td>Copy default</td>
<td>DEFLTCPLO</td>

<tbody>
<tr>
<td>MISCELLANEOUS (continued)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sweep start</td>
<td>SWPSTART</td>
<td>1</td>
<td></td>
<td>This OPC-compatible command initiates a sweep and immediately releases the HP-IB bus, allowing the analyzer to initiate data output as soon as the appropriate data is ready. Use in conjunction with Take4 mode only.</td>
</tr>
<tr>
<td>Collect raw data</td>
<td>TAKE4&lt;ON</td>
<td>OFF&gt;</td>
<td>2,0</td>
<td></td>
</tr>
<tr>
<td>Self test</td>
<td>TST?</td>
<td>1</td>
<td></td>
<td>Causes a self test. Returns a zero if the test passes.</td>
</tr>
<tr>
<td>No operation</td>
<td>NOOP</td>
<td>1</td>
<td></td>
<td>Creates a cycle that has no operation. OPC compatible.</td>
</tr>
<tr>
<td>Select 1-port cal</td>
<td>CAL1</td>
<td>1</td>
<td></td>
<td>Provides access to functions within the 1-port cal menu. (HP 8510 compatibility.)</td>
</tr>
<tr>
<td>External trigger</td>
<td>EXTTHIGH</td>
<td>1</td>
<td></td>
<td>Sets the trigger polarity high.</td>
</tr>
<tr>
<td></td>
<td>EXTTLow</td>
<td>1</td>
<td></td>
<td>Sets the trigger polarity low.</td>
</tr>
<tr>
<td>Wait</td>
<td>WAIT</td>
<td>1</td>
<td></td>
<td>Makes the analyzer wait for a clean sweep when used with the OPC command.</td>
</tr>
</tbody>
</table>

#### INPUT

<p>| Error-corrected Data | INPUDATA[D] | 3 | D | Inputs error-corrected data.                                               |
| Formatted Data      | INPUFORM[D] | 3 | D | Inputs formatted data.                                                     |
| Raw Data            | INPURA1[D]  | 3 | D | Inputs raw data.                                                          |
|                     | INPURA2[D]  | 3 | D |                                                                                |
|                     | INPURA3[D]  | 3 | D |                                                                                |
|                     | INPURA4[D]  | 3 | D |                                                                                |
| Error coefficient   | INPUCALC&lt;01, 02, ... 12&gt; | 2 |    | Inputs an individual error coefficient array. Issue the command CAL1XXX; (XXX specifies the data calibration type), then enter each of the appropriate individual error coefficients using INPUCALC. Finally, issue SAVC; and trigger a sweep. |
|                     | SAVC          | 1 |    | This OPC compatible command denotes completion of the error coefficients transfer to the instrument. |
| Power meter cal.    | INPUMCALC&lt;D&gt; | 3 |    | Inputs power meter cal array. Values should be entered as 100 times the power meter reading in dB. |
| Cal kit             | INPUCALK[D]  | 3 | D | Input a cal kit.                                                          |
| Learn string        | INPULEAS[D]  | 3 | D | Inputs the learn string. Preceded by SELL if learn string is not current revision. |</p>

### Alphabetical Mnemonic Listing

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB</td>
<td>Measures and displays A/B on the active channel.</td>
</tr>
<tr>
<td>ADAP1[D]</td>
<td>Sets adapter electrical delay.</td>
</tr>
<tr>
<td>ADDRCONT[D]</td>
<td>Controller HP-IB address: the address where control is returned after a pass control.</td>
</tr>
<tr>
<td>ADDRDISQ[D]</td>
<td>Disk HP-IB address.</td>
</tr>
<tr>
<td>ADDRLSRC[D]</td>
<td>LO Source HPIB address.</td>
</tr>
<tr>
<td>ADDRPERI[D]</td>
<td>Peripheral HP-IB address (for sequencing). See also TITTPERI.</td>
</tr>
<tr>
<td>ADDRPLT[D]</td>
<td>Plotter HP-IB address.</td>
</tr>
<tr>
<td>ADDRPOWM[D]</td>
<td>Power meter HP-IB address.</td>
</tr>
<tr>
<td>ADDRPRIN[D]</td>
<td>Printer HP-IB address.</td>
</tr>
<tr>
<td>ADPTCOAX</td>
<td>Sets adapter to COAXial.</td>
</tr>
<tr>
<td>ADPTWAVE</td>
<td>Sets adapter to WAVEguide.</td>
</tr>
<tr>
<td>ALC</td>
<td>ALC control.</td>
</tr>
<tr>
<td>ALTAB</td>
<td>Places the analyzer in the alternate inputs measurement mode, where measurements are made on alternate sweeps. See also CHOPAB.</td>
</tr>
<tr>
<td>ANAB&lt;ON</td>
<td>OFF&gt;</td>
</tr>
<tr>
<td>ANAI[D]</td>
<td>Measures and displays the data at the auxiliary input (ANALOG IN).</td>
</tr>
<tr>
<td>AR</td>
<td>Measures and displays A/R on the active channel.</td>
</tr>
<tr>
<td>ASEG</td>
<td>Uses all segments for list frequency sweep. See also SEG[D].</td>
</tr>
<tr>
<td>ASSS</td>
<td>Assert the sequence status bit.</td>
</tr>
<tr>
<td>ATTP1</td>
<td>Selects the amount of attenuation at PORT 1 (Option 011 with test set only).</td>
</tr>
<tr>
<td>ATTP2</td>
<td>Selects the amount of attenuation at PORT 2 (Option 011 with test set only).</td>
</tr>
<tr>
<td>AUTO</td>
<td>Auto scale the active channel.</td>
</tr>
<tr>
<td>AVERFACT[D]</td>
<td>Sets the averaging factor on the active channel.</td>
</tr>
<tr>
<td>AVERO&lt;ON</td>
<td>OFF&gt;</td>
</tr>
<tr>
<td>AVERREST</td>
<td>Restart the averaging on the active channel.</td>
</tr>
<tr>
<td>BACI[D]</td>
<td>Sets the background intensity of the display.</td>
</tr>
<tr>
<td>BANDPASS</td>
<td>Selects the time domain bandpass mode.</td>
</tr>
<tr>
<td>BEEPDONE&lt;ON</td>
<td>OFF&gt;</td>
</tr>
</tbody>
</table>

These 3 commands control the warning beeper, causing it to sound if the indicated condition occurs:
BEEPFAIL<ON|OFF>  A limit test failure.
BEEPWARN<ON|OFF>  The generation of a warning message.

BLAD<ON|OFF>  Blanks the display.
BR  Measures and displays B/R on the active channel.

These commands set the open capacitance values of an open circuit while it is being defined as a calibration standard:

C0[D]
C1[D]
C2[D]
C3[D]

CAL1  Accepted for compatibility with the HP 8510, where its function is to begin a calibration sequence.

These commands set the power meter calibration factor corrections for the particular sensor used. Sensor B is only valid for the HP 438A which has two input channels:

CALFCALF[D]  Sets the calibration factor.
CALFFREQ[D]  Selects the frequency for the calibration factor correction.
CALFSENA  Edits the sensor A calibration factor table.
CALFSENB  Edits the sensor B calibration factor table.

These commands begin a calibration sequence:

CALIFUL2  Short, load, open, thru (SLOT) 2-port.
CALIONE2  One-path 2-port.
CALIRAI  Response and isolation.
CALIRESP  Response.
CALIS111  S11 1-port.
CALIS221  S22 1-port.
CALITRL2  Thru, reflect, line or Line, reflect, match (TRL*/LRM*) 2-port.

These commands select a default calibration kit:

CALK24MM  2.4-mm (HP 85056A/D cal kit).
CALK292MM  2.92-mm.
CALK292S  2.92* (HP 85056K cal kit).
CALK35MD  3.5-mm (HP 85052B/D, HP 85033D cal kit).
CALK35MC  3.5-mm (HP 85033C cal kit).

Note  CALK35MM selects the HP 85033C cal kit for the HP 8752C/53D.

CALK7MM  7-mm (HP 85031B cal kit and HP 85050 series).
CALKN50  Type-N 50 ohm (HP 85032B/E cal kit).
CALKN75  Type-N 75 ohm (HP 85036B/E cal kit).
CALKTRLK TRL 3.5-mm (HP 85052C cal kit).
CALKUSED User-defined calibration kit.

CALN  Calibration: none. Turns calibration type to off.
CALPOW  Provides access to the power meter calibration functions.
CALSPORT1  Recalls cal set associated with Port 1 for adapter removal.
CALSPORT2  Recalls cal set associated with Port 2 for adapter removal.
CALZLINE  Establishes the line or match standard(s) as the characteristic impedance for a TRL/LRM calibration.
CALZSYST[D]  Establishes the system \( Z_0 \) (see SETZ) as the characteristic impedance for a TRL/LRM calibration.
CBRI[D]  Adjusts the color brightness of the selected display feature. (See COLOXXX commands.)
CENT[D]  Sets the center stimulus value. If a list frequency segment is being edited, sets the center of the list segment.
CHAN1  Makes channel 1 the active channel. OPC-compatible.
CHAN2  Makes channel 2 the active channel. OPC-compatible.
CHOPAB  Places the analyzer in the chop measurement mode. See also ALTAB.
CLAD  Class done, modify cal kit, specify class.

These commands call reflection standard classes during a calibration sequence. If only one standard is in the class, it is measured. If there is more than one, the standard being used must be selected with STAN<\A|B|C|D|E|F|G>. If there is only one standard in the class, these commands are OPC-compatible.

CLASS11A  S11A: S11 1-port, opens.
CLASS11B  S11B: S11 1-port, shorts.
CLASS11C  S11C: S11 1-port, loads.
CLASS22A  S22A: S22 1-port, opens.
CLASS22B  S22B: S22 1-port, shorts.
CLASS22C  S22C: S22 1-port, loads.

These commands (OPC-compatible) clear the indicated save/recall registers:
CLEA1  Clears save/recall register 1.
CLEA2  Clears save/recall register 2.
CLEA3  Clears save/recall register 3.
CLEA4  Clears save/recall register 4.
CLEA5  Clears save/recall register 5.
CLEAL  Clears the limit line list. Should be preceded by EDITLIML.
CLEARALL       Clears all the save/recall registers. OPC-compatible.

CLEABIT[D]     Clears the specified bit on the GPIO.
CLEAREG<1>     Clears save/recall registers 01 through 31. CLEAREG01 through CLEAREG05 are the same as CLEA1 through CLEA5. OPC-compatible.

These commands clear the sequence from the internal registers:
CLEASEQ1       Sequence 1.
CLEASEQ2       Sequence 2.
CLEASEQ3       Sequence 3.
CLEASEQ4       Sequence 4.
CLEASEQ5       Sequence 5.
CLEASEQ6       Sequence 6.

CLEL           Clear the currently selected list. This could be a frequency list, power loss list, or limit test list.

CLES           Clears the status register, the event-status registers, and the enable registers.

CLS            Same as CLES.

COAD           Selects coaxial electrical delay. See also WADV.

COAX           Selects coaxial offsets instead of waveguide while defining a standard during a cal kit modification.

These commands select the indicated display feature for color modification:
COLOCH1D       Channel 1 data and limit lines.
COLOCH1M       Channel 1 memory.
COLOCH2D       Channel 2 data and limit lines.
COLOCH2M       Channel 2 memory.
COLOGRAT       Graticule.
COLOTEXT       Text.
COLOWARN       Warning.

COLOR[D]       Adjusts the color saturation for the selected display feature.
CONS           Continues the paused sequence.
CONT           Continuous sweep trigger mode.

These 6 commands convert the S-parameter data to:
CONVIDS        Inverted S-parameters.
CONVOFF        Conversion OFF.
CONVYREF       Y reflection.
CONVYTRA  Y:transmission.
CONVZREF  Z:reflection.
CONVZTRA  Z:transmission.

COPYFRFT  Copies labels from file titles.
COPYFRRT  Copies labels from register titles.
CORI<ON|OFF>  Turns interpolative error correction ON and OFF.
CORR<ON|OFF>  Turns error correction ON and OFF.
COUC<ON|OFF>  Couples and uncouples the stimulus between the channels.
COUP<ON|OFF>  Couple the power when coupled channels is turned OFF, COUCOFF.
CSWI<ON|OFF>  Selects test set continuous switching (ON) or test set hold (OFF) when there is a 2-port calibration active. Continuous switching is allowed only when the power ranges on both attenuator ports are set the same. When continuous switching is ON, the analyzer measures all four S-parameters each time before displaying the data for a full 2-port cal measurement. In test set hold mode, the analyzer measures all four S-parameters once and then measures the desired parameter continuously. This is known as a fast 2-port cal measurement and it is less accurate than a full 2-port calibrated measurement.

CWFREQ[D]  Sets the CW frequency for power sweep and CW frequency modes. While the list frequency table segment is being edited, it sets the center frequency of the current segment.

CWTIME  Selects the CW time sweep type.

DIVD2<ON|OFF>  This command divides the data in channel 2 by the data in channel 1 and displays the result on channel 2. Dual display must be on (DUALCON). DSTOREf  Stores trace in channel memory. OPC-compatible. OPC-compatible.
DCONV  Selects down converter for mixer measurements.
DEBU<ON|OFF>  Turns the HP-IB debug mode ON and OFF. When ON, the analyzer scrolls incoming HP-IB commands across the display.
DECRLOOC  Decrements the sequencing loop counter by 1.
DEFC  Sets the default colors for all display features.
DEFLPRINT
Sets the printer to the following default setup conditions:

<table>
<thead>
<tr>
<th>Print</th>
<th>Monochrome</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto-feed</td>
<td>On</td>
</tr>
<tr>
<td>Print Colors:</td>
<td></td>
</tr>
<tr>
<td>Ch 1 Data</td>
<td>Magenta</td>
</tr>
<tr>
<td>Ch 1 Memory</td>
<td>Green</td>

<tr>
<td>Ch 2 Data</td>
<td>Blue</td>
</tr>
<tr>
<td>Ch 2 Memory</td>
<td>Red</td>
</tr>
<tr>
<td>Graticule</td>
<td>Cyan</td>
</tr>
<tr>
<td>Warning</td>
<td>Black</td>
</tr>
<tr>
<td>Text</td>
<td>Black</td>
</tr>
</tbody>
</table>

DEFLTCPIO
Sets up the following default state for copy. There is no equivalent front-panel key.

<table>
<thead>
<tr>
<th>Plotter Type:</th>
<th>PLOTTER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Printer Type:</td>
<td>DESKJET</td>

<tr>
<td>HP-IB Address:</td>
<td>1</td>
</tr>
<tr>
<td>Parallel Port:</td>
<td>COPY</td>
</tr>
</tbody>
</table>

DEFS[D]
Begin standard definition during cal kit modification. D is the standard number.

DELA
Displays the data formatted as group delay.

DELO
Turns the delta marker mode OFF.

These 6 commands make the indicated marker the delta reference:

DELR1   Marker 1.
DELR2   Marker 2.
DELR3   Marker 3.
DELR4   Marker 4.
DELR5   Marker 5.
DELRFIXM Fixed marker.

DEMOAMPL Turns on transform demodulation and sets the transform demodulation to amplitude demodulation. Only has a meaningful effect with a CW time transform.

DEMOOFF Turns the transform demodulation function OFF.
DEMOPHAS  Sets the transform demodulation to phase demodulation. Only has a meaningful effect with a CW time transform.

DFLT  Sets the plotter to the following default setup conditions:

<table>
<thead>
<tr>
<th>Plot Data</th>
<th>On</th>
<th>Pen Number:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plot Mem</td>
<td>On</td>
<td>Data 2</td>
</tr>
<tr>
<td>Plot Grat</td>

<tr>
<td>Auto-feed</td>
<td>On</td>
<td>Marker 7</td>
</tr>
<tr>
<td>Scale Plot</td>
<td>Full</td>
<td>Line Type:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Data 7</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Memory 7</td>
</tr>
</tbody>
</table>

DIRS[D]  Sets the number of files in the directory at disk initialization. LIF only.

DISCUNIT[D]  Specifies which disk in an external multiple-disk drive to be used for save/reCALL.

DISCVOLU[D]  Specifies which volume of an external multiple-volume disk drive to be used for save/reCALL.

DISM<ON|OFF>  When on, displays the response and stimulus values for all markers that are turned on; when off, only the active marker’s value is displayed.

These 6 commands display the indicated combinations of data and trace memory on the active channel:

DISPDAT  Data only.
DISPDATM  Data and memory.
DISPDDM  Data divided by memory (linear division, log subtraction).
DISPDM  Memory only.
DISPMEMO  Data minus memory (linear subtraction).
DIVI  Same as DISPDDM.

DONE  Done with a class of standards, during a calibration. Only needed when multiple standards are measured to complete the class.

DONM  Done modifying a test sequence.

DOSEQ<1>  Begins execution of the selected sequence, I = 1 to 6.

DOWN  Decrements the value in the active entry area (down key).

DUAC<ON|OFF>  Dual channel display ON or OFF.

DUPLSEQ[X|SEQ[Y]  Duplicates sequence X to sequence Y. X,Y = 1 to 6.

EDITDONE  Done editing list frequency or limit table.
EDITLML Begins editing limit table.
EDITLIST Begins editing list frequency table.
ELED[D] Sets the electrical delay offset.
EMIB Send out a beep during a sequence.
ENTO Turns the active entry area OFF.
ESB? Outputs event-status register B.
ESE[D] Enables the selected event-status register bits to be summarized by bit 5 in the status byte. An event-status register bit is enabled when the corresponding bit in the operand D is set.
ESNB[D] Enables the selected event-status register B bits to be summarized by bit 2 of the status byte. A bit is enabled in the register when the corresponding bit in the operand D is set.
ESR? Outputs the value of the event-status register.
EXTD Selects the external disk as the active storage device.

These commands include the indicated information when a register is stored on disk. See Figure 1-4 for data types:

EXTMDATA<ON|OFF> Adds error corrected data (real and imaginary pairs) along with the other files.
EXTMDATO<ON|OFF> Error corrected data array only (real and imaginary pairs).
EXTMFORM<ON|OFF> Formatted trace data. Uses currently selected format for data.
EXTMGRA<ON|OFF> User graphics.
EXTMRAW<ON|OFF> Raw data arrays (real and imaginary pairs).

EXTTHIGH Sets the external trigger line high.
EXTTLOW Sets the external trigger line low.
EXTTOFF Deactivates the external trigger mode. OPC-compatible.
EXTTON Activates the external trigger mode.
EXTTPPOIN Sets the external trigger to auto trigger on point. OPC-compatible.
FIXE Specifies a fixed load, as opposed to a sliding load or offset load, when defining a standard during a cal kit modification.

These 5 commands set the data format for array transfers in and out of the instrument:

FORM1 HP 8753D internal format. Preceded by 4 byte header.
FORM2 32 bit floating point format. Preceded by 4 byte header.
FORM3 64 bit floating point format. Preceded by 4 byte header.
FORM4 ASCII format. No header.
FORM5 32 bit floating point PC format. Bytes reversed. Preceded by 4 byte header.

These commands define the format to use on disk initializations:

FORMATDOS Selects DOS as the disk format.
FORMATLIF  Selects LIF as the disk format.

FREQOFFS<ON|OFF>  Activates the frequency offset instrument mode. OPC-compatible.
FREO  Frequency blank. Turns OFF frequency notation.
FRER  HP-IB free run. Acts the same as CONT;.
FULP  Selects full page plotting, as opposed to plotting in one of the four quadrants.

These 3 commands select a forward calibration class, during a 2-port calibration sequence.
They are OPC-compatible if there is only one standard in the class:

FWDI  Isolation.
FWDM  Match.
FWDT  Transmission.

These 5 commands control the time domain gate:

GATECENT[D]  Center time.
GATEO<ON|OFF>  Gate ON/OFF. OPC-compatible.
GATESPAN[D]  Span time.
GATESTAR[D]  Start time.
GATESTOP[D]  Stop time.

These 4 commands set the gate shape:

GATSMAXI  Maximum.
GATSMINI  Minimum.
GATSNORM  Normal.
GATSWIDE  Wide.

GOSUB<I>  Invokes a sequence as a subroutine. I = 1 to 6.

These commands activate the harmonic measurement mode, Option 002. They are all OPC-compatible:

HARMOFF  Turns OFF harmonic mode. OPC-compatible.
HARMSEC  Measures the second harmonic. OPC-compatible.
HARMTHIR  Measures the third harmonic. OPC-compatible.

HOLD  Puts the sweep trigger into hold.

IDN?  Outputs the identification string: HEWLETT PACKARD, 87NND, 0, X.XX, where 87NND is the model number of the instrument and X.XX is the firmware revision of the instrument.
These 7 commands branch an executing sequence to a new sequence if the following condition is satisfied.

**IFBIHIGH**  Tests the specified input GPIO bit (see PARAIN[D]). If high, invokes the sequence which follows.

**IFBILOW**  Tests the specified input GPIO bit (see PARAIN[D]). If low, invokes the sequence which follows.

**IFBW[D]**  Sets the IF bandwidth.

**IFLCQESEQ<>I<>**  If loop counter equals zero, then do the sequence that follows.

**IFLCNESEQ<>I<>**  If loop counter does not equal zero, then do the sequence that follows.

**IFLTFAILSEQ<>I<>**  If limit test fails, then do sequence that follows.

**IFLTPASSSEQ<>I<>**  If limit test passes, then do sequence that follows.

**IMAG**  Selects the imaginary display format.

**INCRLOOC**  Increments the sequencing loop counter by 1.

**INID**  Initializes the internal disk. All previous information on the disk will be destroyed.

**INIE**  Initializes the external disk. All previous information on the disk will be destroyed. Requires pass control when using the HP-IB port.

These commands input an individual error coefficient array. Before sending an array, issue a CALIXXX; command, where XXXX specifies the calibration type of the data. Then input the array or arrays. Lastly store the data with SAVC; . The instrument goes into hold, displaying uncorrected data. Complete the process by triggering a sweep. See Table 1-7, for the contents of the different arrays.

**INPUCALC01[D]**  Array 1.

**INPUCALC02[D]**  Array 2.

**INPUCALC03[D]**  Array 3.

**INPUCALC04[D]**  Array 4.

**INPUCALC05[D]**  Array 5.

**INPUCALC06[D]**  Array 6.

**INPUCALC07[D]**  Array 7.

**INPUCALC08[D]**  Array 8.

**INPUCALC09[D]**  Array 9.

**INPUCALC10[D]**  Array 10.

**INPUCALC11[D]**  Array 11.

**INPUCALC12[D]**  Array 12.

**INPUCLK[D]**  Inputs a cal kit read out with OUTCALK; . After the transfer, the data should be saved into the user cal kit area with SAVEUSEK;.

**INPUDATA[D]**  Inputs an error corrected data array, using the current setting of the FORM command.
INPUFORM[D] Inputs a formatted data array, using current the current setting of the FORM command.

INPULEAS[D] Inputs a learn string read out by OUTPLEAS.

These commands input power meter calibration arrays into the instrument. Values should be entered as 100 × power meter reading in dB.

INPUMPICAL1 Channel 1.

INPUMPICAL2 Channel 2.

These commands input a raw data array using the current format. See OUTPRAW for the meaning of the arrays. The instrument stops sweeping, error corrects the data, then formats and displays the data.

INPURAW1[D] Array 1.

INPURAW2[D] Array 2.

INPURAW3[D] Array 3.

These commands select the instrument mode. They are all OPC-compatible:

INSMEXSA External source, auto. OPC-compatible.

INSMEXSM External source, manual. OPC-compatible.

INSMNENA Standard network analyzer. OPC-compatible.

INSMTUNR Tuned receiver. OPC-compatible.

INTD Selects the internal disk as the active storage device.

INTD[D] Sets the display intensity, 50 to 100 percent.

INTM Selects the internal memory for save/recall.

ISOD Done with isolation subsequence in a 2-port calibration. OPC-compatible.

ISOL Begins the isolation subsequence step in a 2-port calibration.

ISOOP Selects isolation for one path, two port calibration.

KEY[D] Sends a keycode, equivalent to actually pressing the key. It does not matter if the front-panel is in remote mode. See Figure 1-6 for the key codes.

KTID Calibration kit done This is the last step in modifying a cal kit.

KOR? Outputs last key code or knob count. If the reply is positive, it is a key code. If it is negative, then set bit 15 equal to bit 14, and the resulting two byte integer is the RPG knob count. It can be either positive or negative. There are about 120 counts per turn.

These commands enter labels for the standard classes during a cal kit modification:

LABEFWDM[$] Forward match.

LABEFWDI[$] Forward transmission.

LABERESI[$] Response, response and isolation.
LABERESP[$]  
Response.

LABEREVM[$]  
Reverse match.

LABEREVT[$]  
Reverse transmission.

LABES11A[$]  
S11A (opens).

LABES11B[$]  
S11B (shorts).

LABES11C[$]  
S11C (loads).

LABES22A[$]  
S22A (opens).

LABES22B[$]  
S22B (shorts).

LABES22C[$]  
S22C (loads).

LABETRL[$]  
TRL line or match.

LABETRLT[$]  
TRL thru.

LABETRLR[$]  
TRL reflect.

LABETLFM[$]  
TRL, Line, Forward, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETLFT[$]  
TRL, Line, Forward, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETLRM[$]  
TRL, Line, Reverse, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETLRT[$]  
TRL, Line, Reverse, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETRFM[$]  
TRL, Reflect, Forward, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETRRM[$]  
TRL, Reflect, Reverse, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETTFM[$]  
TRL, Thru, Forward, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETTFT[$]  
TRL, Thru, Forward, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETTRM[$]  
TRL, Thru, Reverse, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABETTRT[$]  
TRL, Thru, Reverse, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.

LABK[$]  
Enters a cal kit label during a cal kit modification.

LABS[$]  
Enters a standard's label during standard definition.

LEFL  
Selects a plot in the left lower quadrant.

LEFU  
Selects a plot in the left upper quadrant.

LIMIAMP[$]  
Enters the limit line amplitude offset.

LIMILINE<$|OFF>  
Turns the display of the limit lines ON and OFF.
LIMMAOF  Marker to limit offset. Centers the limit lines about the current marker position using the limit amplitude offset function.

LIMISTIO[D]  Enters the stimulus offset of the limit lines.

LIMITEST<ON|OFF>  Turns limit testing ON and OFF.

These 8 commands edit a limit test segment. The limit table editing is begun with EDITLIML; and a segment is brought up for editing with SEDI N; or added using SADD; . The segment is closed with SDON ; , the table is closed with EDITDONE ;

LIMD[D]  Sets the limit delta value while editing a limit line segment.

LIML[D]  Sets the lower limit value.

LIMM[D]  Sets the middle limit value.

LIMS[D]  Sets the limit stimulus break point.

LIMTFL  Makes the segment a flat line.

LIMTSL  Makes the segment a sloping line.

LIMTSP  Makes the segment a single point.

LIMU[D]  Sets the upper limit value.

LINFREQ  Selects a linear frequency sweep.

LINM  Selects the linear magnitude display format.

LINTDATA[D]  Enters the line type for plotting data.

LINTMEMO[D]  Enters the line type for plotting memory.

LISFREQ  Selects the list frequency sweep mode.

LISV  Activates the list values function. The next page of values can be called with NEXP ; and the previous page can be called with PREP ; . The current page can be plotted or printed, in raster graphics mode, with PLIT ; or PRINALL ; respectively. The entire list can be printed, in ASCII text mode, with PRINTALL ; . (Since these commands may need to take control of an HP-IB peripheral, the system controller must have pass control capability.)

These 5 commands load the file from disk with the name indicated by the previous TITF n command. The actual file loaded depends on the file title in the file position specified by the TITF n command. Requires pass control mode.

LOAD1  Loads the file from disk using the file name provided by the preceding TITF1 ; command.

LOAD2  Loads the file from disk using the file name provided by the preceding TITF2 ; command.

LOAD3  Loads the file from disk using the file name provided by the preceding TITF3 ; command.

LOAD4  Loads the file from disk using the file name provided by the preceding TITF4 ; command.

LOAD5  Loads the file from disk using the file name provided by the preceding TITF5 ; command.
These 6 commands load the file from disk with the name indicated by the previous TITSEQn
command. The actual file loaded depends on the file title in the file position specified in the
TITSEQn command. Requires pass control mode.

LOADSEQ1  Loads sequence 1 from disk.
LOADSEQ2  Loads sequence 2 from disk.
LOADSEQ3  Loads sequence 3 from disk.
LOADSEQ4  Loads sequence 4 from disk.
LOADSEQ5  Loads sequence 5 from disk.
LOADSEQ6  Loads sequence 6 from disk.

LOAN  Measures the load as not being offset when a standard has been
defined as an offset load (see OFLS).
LOAO  Measures the load as being offset when a standard has been defined
as an offset load (see OFLS).
LOCONT<ON|OFF>  Turns external LO control on/off.
LOFREQ[D]  Sets the LO frequency.
LOFSTAR[D]  Sets the LO start frequency.
LOFSTOP[D]  Sets the LO stop frequency.
LOFSWE  Selects the LO sweep frequency mode.
LOGFREQ  Selects a log frequency sweep.
LOGM  Selects the log magnitude display format.
LOOQ[D]  Sets the value of the sequencing loop counter.
LOPOWER[D]  Sets the LO power level.
LOPSTAR[D]  Sets the LO start power level.
LOPSTOP[D]  Sets the LO stop power level.
LOPSWE  Selects sweep power mode.
LOWPIMPU  Turns ON the low pass impulse transform.
LOWPSTEP  Turns ON the low pass step transform.
LRN?  Same as OUTPLEAS (output learn string).
LRN[D]  Same as INPULEAS (input learn string).
MANTRIG  Sets the external trigger to manual trigger on point.
           OPC-compatible.
These commands make the indicated marker active and set its stimulus value:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MARK2[D]</td>
<td>Marker 2.</td>
</tr>
<tr>
<td>MARK3[D]</td>
<td>Marker 3.</td>
</tr>
<tr>
<td>MARK5[D]</td>
<td>Marker 5.</td>
</tr>
<tr>
<td>MARKBUCK[D]</td>
<td>Places the active marker on a specific sweep point (bucket). D is the bucket number, ranging from 0 to number of points less 1.</td>
</tr>
<tr>
<td>MARKCENT</td>
<td>Sets the center stimulus value to that of the active marker’s stimulus value.</td>
</tr>
<tr>
<td>MARKCONT</td>
<td>Places the markers continuously on the trace, not on discrete points (interpolates the marker values between discrete points).</td>
</tr>
<tr>
<td>MARKCOUP</td>
<td>Couples the markers between the channels, as opposed to MARKUNCO.</td>
</tr>
<tr>
<td>MARKCW</td>
<td>Sets the CW frequency to the active marker’s frequency.</td>
</tr>
<tr>
<td>MARKDELA</td>
<td>Sets electrical length so group delay is zero at the active marker’s stimulus.</td>
</tr>
<tr>
<td>MARKDISC</td>
<td>Places the markers on the discrete measurement points.</td>
</tr>
<tr>
<td>MARKFAUV[D]</td>
<td>Sets the auxiliary value of the fixed marker position. Works in coordination with MARKFVAL and MARKFSTI.</td>
</tr>
<tr>
<td>MARKFSTI[D]</td>
<td>Sets the stimulus position of the fixed marker.</td>
</tr>
<tr>
<td>MARKFVAL[D]</td>
<td>Sets the value of the fixed marker position.</td>
</tr>
<tr>
<td>MARKMAXI</td>
<td>Same as SEAMAX (search for maximum on current channel’s trace).</td>
</tr>
<tr>
<td>MARKMIDD</td>
<td>During a limit segment edit, makes the marker amplitude the limit segment middle value.</td>
</tr>
<tr>
<td>MARKMINI</td>
<td>Same as SEAMIN (search for minimum on current channel’s trace).</td>
</tr>
<tr>
<td>MARKOFF</td>
<td>Turns all markers and marker functions OFF.</td>
</tr>
<tr>
<td>MARKREF</td>
<td>Sets the reference value to that of the active marker’s amplitude.</td>
</tr>
<tr>
<td>MARKSPAN</td>
<td>Sets the span for the entire trace to that of the span between the active marker and the delta reference marker.</td>
</tr>
<tr>
<td>MARKSTAR</td>
<td>Sets the start stimulus to that of the active marker’s.</td>
</tr>
<tr>
<td>MARKSTIM</td>
<td>During a limit segment edit, sets the limit stimulus break point to that of the active marker’s.</td>
</tr>
<tr>
<td>MARKSTOP</td>
<td>Sets the stop stimulus to that of the active marker’s.</td>
</tr>
<tr>
<td>MARKUNCO</td>
<td>Uncouples the markers between channels, as opposed to MARKCOUP.</td>
</tr>
<tr>
<td>MARKZERO</td>
<td>Places the fixed marker at the active marker position and makes it the delta reference.</td>
</tr>
<tr>
<td>MAXF[D]</td>
<td>Sets the maximum valid frequency of a standard being defined during a cal kit modification.</td>
</tr>
</tbody>
</table>
MEASA  Measures and displays input A on the active channel.
MEASB  Measures and displays input B on the active channel.
MEASR  Measures and displays input R on the active channel.
MEASTAT<ON|OFF>  Turns trace statistics ON and OFF.
MENU<ON|OFF>  Blanks the softkey menu. Use with caution, as this may give unusual results when setting up an instrument state. Recommend setting up states using MENU<ON> (default) and, when setup is complete, using MENU<OFF>.

These commands bring up the menu associated with the indicated front-panel key:

MENUAVG  AVG
MENUCAL  CAL
MENUCOPY  COPY
MENUDISP  DISPLAY
MENUFORM  FORMAT
MENUMARK  MARKER
MENUMEAS  MEAS
MENUMRKF  MARKER FCTN
MENURECA  SAVE RECALL
MENUSAVE  SAVE RECALL
MENUSCAL  SCALE
MENUSEQU  SEQUENCE
MENUSTIM  STIMULUS MENU
MENUSYST  SYSTEM
MINF[D]  Sets the minimum valid frequency of a standard being defined during a cal kit modification.
MINU  Displays data minus memory, the same as DISPDMM.
MINMAX<ON|OFF>  Enables/disables min/max recording per segment. Min and max values are recorded per limit segment. Limit testing need not be active.
MODI1  Begins the modify cal kit sequence.
MODS  Compute new cal set using adapter removal.

NEWSEQ<I>  Begins modifying a sequence.
NEXP  Displays the next page of the operating parameters list.
NOOP  No operation. OPC-compatible.
NUMG[D]  Activates D number of groups of sweeps. A group is whatever is needed to update the current parameter once. This function restarts averaging if ON. OPC-compatible.
NUMR[D]  Sets the number of power meter readings per point used during a power meter calibration.
OFLD           Offset loads done.

OFLS           Selects the calibration standard load as being an offset load, as opposed to a sliding or fixed load, during a cal kit modification.

These 3 commands specify the offset value for the indicated parameter for a standard being defined during a cal kit modification:

OFS{D[D]}      Delay offset.
OFS{D[D]}      Loss offset.
OFS{D[D]}      Impedance offset.

OMII           Omits the isolation step of a calibration sequence.

OPC            Operation complete. Reports the completion of the next command received by setting bit 0 in the event-status register, or by replying to an interrogation if OPC?; is issued.

OPEP           Presents a list of key operating parameters. NEXP; calls the next page of parameters and the previous page can be called with PREP;.. Requesting a plot or print copies the current page. The current page can be plotted or printed, in raster graphics mode, with PL{D[T]; or PR{D{NALL}; respectively. The entire list can be printed, in ASCII text mode, with PRINTALL;. Since these commands need to take control of an HP-IB peripheral, the system controller must have pass control capability.

OUTPACTII       Outputs the value of the active function, or the last active function if the active entry area is OFF.

OUTPAMAX       Outputs the max values for all limit line segments.

OUTPAMIN       Outputs the min values for all limit line segments.

OUTPAPER       Outputs the smoothing aperture in stimulus units, rather than as a percentage.

These 12 commands output an error correction array for the active calibration on the active channel. See Table 1-7, for the contents of each array. Each array is output in the currently set form determined by the FORMn command. The data is in real/imaginary pairs, the same number of pairs as points in the sweep.

OUTPCALCO1     Array 1.
OUTPCALCO2     Array 2.
OUTPCALCO3     Array 3.
OUTPCALCO4     Array 4.
OUTPCALCO5     Array 5.
OUTPCALCO6     Array 6.
OUTPCALCO7     Array 7.
OUTPCALCO8     Array 8.
OUTPCALCO9     Array 9.
OUTPCALCO10    Array 10.
OUTPCALC11 Array 11.
OUTPCALC12 Array 12.

OUTPCALK Outputs the currently active calibration kit, as a less than 1000 byte string. The data is in FORM 1.
OUTPCHAN Outputs the active channel number.
OUTPDATA Outputs the error corrected data from the active channel. See Figure 1-4 and FORMn command.
OUTPDATF Fast data transfer command for OUTPDATA.
OUTPDATP Outputs the trace data indexed by point (see SELPT[D]).
OUTPDATR Outputs the trace data for range of points (see SELMINPT[D], SELMAXPT[D]).
OUTPERRO Outputs the oldest error message in the error queue. Sends first the error number, and then the error message itself as a string no longer than 50 characters.
OUTPFAP This command is similar to OUTPLIMF except that it reports the number of failures first, followed by the stimulus and trace values for each failed point in the test.
OUTPFORM Outputs the formatted display data array from the active channel. See Table 1-3 for the contents of the array as a function of display format. See also FORMn command.
OUTPFORF Fast data transfer command for OUTPFORM.

These 12 commands output an interpolated error coefficient array for the active calibration on the active channel. See Table 1-8 for the contents of each array.

OUTPICAL01 Array 1.
OUTPICAL02 Array 2.
OUTPICAL03 Array 3.
OUTPICAL04 Array 4.
OUTPICAL05 Array 5.
OUTPICAL06 Array 6.
OUTPICAL07 Array 7.
OUTPICAL08 Array 8.
OUTPICAL09 Array 9.
OUTPICAL10 Array 10.
OUTPICAL11 Array 11.
OUTPICAL12 Array 12.

OUTPIDEN Outputs the identification string for the analyzer: HEWLETT PACKARD, 87NNND, O.X.XX where 87NNND is the model number of the instrument and X.XX is the firmware revision of the instrument.
These 2 commands output the interpolated power meter calibration arrays for channels 1 and 2:

**OUTPMCL1** Channel 1.
**OUTPMCL2** Channel 2.

**OUTKEY** Outputs the key code of the last key pressed. An invalid key is reported with a 63, a knob turn with a -1. See Figure 1-6 for the front-panel key codes.

**OUTPLEAS** Outputs the learn string, which contains the entire front panel state, the limit table, and the list frequency table. It is always in binary format not intended for decoding.

**OUTPLIM1** Outputs the status of the limit test for channel 1.
**OUTPLIM2** Outputs the status of the limit test for channel 2.

These 3 commands output the limit test results. The results consist of four fields. First is the stimulus value for the point. Second is an integer indicating test status. Third is the upper limit at that point. Fourth is the lower limit at that point. If there are no limits at that point, the third and fourth fields are zero. The test status is -1 for no test, 0 for fail, and 1 for pass.

**OUTPLIMF** Outputs the limit test results for each failed point.
**OUTPLIML** Outputs the limit test results for each point in the sweep. This is an ASCII transfer.
**OUTPLIMM** Outputs the limit test results at the marker.

**OUTPMARK** Outputs the marker values. The first two numbers are the marker response values, and the last is the stimulus value. See Table 1-3 for the meaning of the response values as a function of display format.

**OUTPMEMO** Outputs the memory trace from the active channel. The data is in real/imaginary pairs, and can be treated the same as data read with the OUTPDATA command.

**OUTPMEMF** Fast data transfer command for OUTPMEMO.

**OUTPMSTA** Outputs the marker statistics: mean, standard deviation, and peak-to-peak variation in that order. If statistics is not ON, it is turned ON to generate current values and turned OFF again. See also MEASTAT<ON|OFF>.

**OUTPMWID** Outputs the marker bandwidths search results: bandwidth, center, and Q in that order. If widths is not ON, it is turned ON to generate current values and turned OFF again.

**OUTPMWIL** Performs the same operation as OUTPMWID plus appends the loss value as well.

**OUTPOPTS** Outputs an ASCII string of the options installed.

**OUTPLOT** Outputs the plot string. Can be directed to a plotter, or read into the computer.

These commands output the power meter calibration array. Values should be entered as 100 times the power meter reading in dB. A default array is used if a power meter calibration sweep, TAKCS, has not been taken.
OUTPPMCAL1    Channel 1.
OUTPPMCAL2    Channel 2.

These 4 commands output the pre-raw measurement data. See Figure 1-4 for the meaning of
the data. Analogous to OUTPRAW except that pre-raw data has not had sampler correction
nor attenuator offsets applied. These offsets are not necessary for data that will be fully error
corrected. See BASIC programming Example 2E: Take4 — Error Correction Processed on an
External Computer. The arrays hold S11, S21, S12, and S22, respectively:

OUTPPRE1     Array 1 (S11 data).
OUTPPRE2     Array 2 (S21 data).
OUTPPRE3     Array 3 (S12 data).
OUTPPRE4     Array 4 (S22 data).

OUTPPRIN     Outputs a raster dump of the display, intended for a graphics
            printer.

OUTPPRNALL   Outputs all of the List Values or Operating Parameters in text mode.
            Activate the desired function by preceding with LISV or OEP,
            respectively.

These 5 commands output the raw measurement data. See Figure 1-4 for the meaning of the
data. Normally, array 1 holds the current parameter. If a 2-port calibration is active, the arrays
hold S11, S21, S12, and S22, respectively:

OUTPRAW<1>   Fast data transfer command for OUTPRAW<1>.
OUTPRAW1     Array 1 (S11 data).
OUTPRAW2     Array 2 (S21 data).
OUTPRAW3     Array 3 (S12 data).
OUTPRAW4     Array 4 (S22 data).

OUTPRFFF     Outputs the external source RF frequency. The instrument must be
            in external source mode, either INSMEXSA or INSMEXSM.

OUTPSEGAF    Outputs the segment number and its limit test status for all active
            segments.

OUTPSEGM     Outputs the limit test min/max for all segments. Outputs the
            segment number, max stimulus, max value, min stimulus, min value
            for all active segments.

OUTPSEGF     Outputs the limit test status for a specified segment. See
            SELSEG[D].

OUTPSEGGM    Outputs limit test min/max for a specified segment. See SELSEG[D].

OUTPSEQ<1>   Outputs 1’s sequence listing. 1 = 1 to 6.

OUTPSERN     Outputs the serial number of the analyzer.

OUTPSTAT     Outputs the status byte.

OUTPTTIL     Outputs the display title.
PARAIN[D] Specify the input GPIO bit to be used by IFBIHIGH and IFBILOW tests.

PARAL<GPIO|CPY> Selects use of the parallel port: for general purpose I/O or for the copy function.

PARAOUT[D] Programs all GPIO output bits (0 to 255) at once.

PAUS Inserts a pause into a sequence.

PCB[D] Same as ADDRCONT. Indicates where control will be returned after a pass control.

These 7 commands select the color for printing the indicated display feature where <COLOR> is one of the following colors: white, cyan, magenta, blue, yellow, green, red, or black.

PCOLDATA1<COLOR> Channel 1 data.

PCOLDATA2<COLOR> Channel 2 data.

PCOLMEmO1<COLOR> Channel 1 memory.

PCOLMEmO2<COLOR> Channel 2 memory.

PCOLGRAT<COLOR> Graticule.

PCOLTEXT<COLOR> Displays text.

PCOLWARN<COLOR> Warning text.

PDATA<ON|OFF> Selects whether trace data is plotted.

These 5 commands select the pen (value for D) for plotting the indicated display feature for the active channel:

PENNDATA[D] Data trace.

PENNGRAT[D] Graticule.

PENNMARK[D] Markers and marker text.

PENNMEMO[D] Memory trace.

PENNTTEXT[D] Text and user graphics.

PGRAT<ON|OFF> Selects whether the graticule is plotted.

PHA0[D] Sets the phase offset.

PHAS Selects the phase display format.

PLOS<SLow|FAST> Selects the pen speed for plotting. (Slow is useful for transparency plotting.)

PLOT Initiates a plot.

PLTHNDSHK<XON|DTR> Selects the plotter handshake mode as either Xon-Xoff or DTR-DSR.

PLTPRTDISK Sets the plotter port to disk (either internal disk or external disk).

PLTPRTHPIB Sets the plotter port to HP-IB.

PLTPRTPARA Sets the plotter port to parallel.

PLTPRTSERI Sets the plotter port to serial.
PLTTRAUTF<ON|OFF>  Turns ON and OFF the plotter auto feed.
PLTTRBAUD[D]    Sets the plotter baud rate.
PLTTRFORF       Sends a form feed to the plotter.
PLTTYPHPGL      Selects HP-GL compatible printer as the plotter type.
PLTTYPPLTR      Selects plotter as the plotter type.
PMEM<ON|OFF>     Selects whether memory is plotted.
PMKR<ON|OFF>     Selects whether markers are plotted.
PMTRTITI       Reads value from power meter or peripheral at the power meter's HP-IB address into title string.
POIN[D]         Sets the number of points in the sweep.
POLA            Selects the polar display format.
These 3 commands select the marker readout format for polar display:

POLMLIN         Linear markers.
POLMLOG         Log markers.
POLMRI          Real/imaginary markers.

PORE<ON|OFF>     Turn port extensions ON and OFF.
These 4 commands set the port extension length for the indicated port or input. Ports 1 and 2 refer to the test set ports:
PORT1[D]        Port 1.
PORT2[D]        Port 2.
PORTA[D]        Input A.
PORTB[D]        Input B.

PORTP<CPLD|UNCPLD> Selects either coupled or uncoupled for the port powers for a given channel.
PORTR[D]        Same as PORT1.
PORTT[D]        Same as PORT2.
POWE[D]         Sets the output power level. See also PWRR<PAUTO/PMAN>.
POWLFREQ[D]     Selects the frequency for which a power loss correction is entered. This must be followed by a POWLLOSS[D], which sets the value.
POWLLIST        Begins editing a power loss list for a power meter calibration.
POWLLOSS[D]     Sets the loss value for a particular frequency, set by POWLFREQ[D], in the power loss list.
POWM<ON|OFF>    Designates whether the HP 436A (ON) or the HP 437B/438A (OFF) is to be used as the power meter.
POWR<I>         Selects power ranges 00 to 07 when in manual power range.
POWS            Selects power sweep, from the sweep type menu.
POWT<ON|OFF>    Trip power (set maximum attenuation) ON or OFF.
PRAN<i> Selects power ranges 01 to 07 when in manual power range.
PREP Displays the previous page of the operating parameters list.
PRES Presets the analyzer to the factory preset state. OPC-compatible.
PRIC Selects color print (as opposed to monochrome; see also PRIS).
PRINALL Copies the display, in raster graphics mode, to a printer.
PRINSEQ<i> Begins printing the sequence selected.
PRINTALL Prints all list values or operating and marker parameters in ASCII text mode.
PRIS Selects standard (monochrome) print.
PRNINDSHK<XON|DTR> Selects the printer handshake mode as either Xon-Xoff or DTR-DSR.
PRNPRTPIB Sets the printer port to HP-IB.
PRNPRTPARA Sets the printer port to parallel.
PRNPRTSERI Sets the printer port to serial.
PRNTRAUTF<ON|OFF> Turns ON and OFF the printer auto feed.
PRNTRBAUD[D] Sets the printer baud rate.
PRNTRFORF Sends a form feed to the printer.
PRNTYP540 Selects the DeskJet 540 or 850C printer as the printer type.
PRNTYPDJ Selects the DeskJet printer as the printer type.
PRNTYPEP Selects the Epson ESC/P2 printer control language-compatible printer as the printer type.
PRNTYPLJ Selects the LaserJet printer as the printer type.
PRNTYPPJ Selects the PaintJet printer as the printer type.
PRNTYPTJ Selects the ThinkJet printer as the printer type.
PSOFT<ON|OFF> Controls whether softkeys are included in the hardcopy print or plot.
PTEXT<ON|OFF> Selects whether text is plotted.
PTOS Pauses the sequence to be followed by selection one of the 6 sequences (SEQ<i>).</p>

These 5 commands purge the indicated file from disk. Requires pass control mode when using an external disk drive.

PURG1 File 1.
PURG2 File 2.
PURG3 File 3.
PURG4 File 4.
PURG5 File 5.
These 3 commands select the type of power meter calibration desired. A calibration sweep should be taken (TAKCS) after selecting a “one sweep” Power meter calibration, to ensure a valid calibration. No calibration sweep is needed for “each sweep” power meter calibrations.

**PWMCEACS[D]** Each sweep.
**PWMCOFF[D]** Off.
**PWMCONES[D]** One sweep.

**PWRLOSS<ON|OFF>** Selects whether or not to use the power loss table for a power meter calibration.

**PWRMCAL** Displays the power meter cal menu and sets the drive port cal power.

**PWRR<PAUTO|MAN>** Select the power range auto or manual mode.

**Q<I>** Same as SEQ<I>.

**RAID** Completes the response and isolation cal sequence. OPC-compatible.

**RAIISOL** Calls the isolation class for the response and isolation calibration.

**RAIRESP** Calls the response class for the response and isolation calibration.

**RAWOFFS<ON|OFF>** Selects whether sampler and attenuator offsets are ON or OFF. By selecting RAW offsets OFF, a full two port error correction can be performed without including the effects of the offsets. It also saves substantial time at recalls and during frequency changes (see SM8<ON|OFF>). Raw offsets follow the channel coupling. RAWOFFS<ON|OFF> and SAMC<ON|OFF> are linked: when one changes state, so does the other. See BASIC programming Example 2E: Take4 — Error Correction Processed on an External Computer.

**READDATE** Outputs the date in the following string format: DD MMM YYYY. HP-IB only command.

**READTIME** Outputs the time in the following string format: HH:MM:SS. HP-IB only command.

**REAL** Selects the real display format.

**RECO** Recalls previously saved display colors.

These 6 commands (OPC-compatible) recall the indicated internal register.

**RECA1** Register 1.
**RECA2** Register 2.
**RECA3** Register 3.
**RECA4** Register 4.
**RECA5** Register 5.

**RECAREG<I>** Recalls save/recall registers 01 through 31. RECAREG01 through RECAREG05 are the same as RECA1 through RECA5. OPC-compatible.
<table>
<thead>
<tr>

</tbody>
</table>
SAMC  Selects whether sampler correction is ON or OFF. SAMC<ON|OFF> and RAWOFFS<ON|OFF> are linked: when one changes state, so does the other.

SAV1  Completes the 1-port calibration sequence. OPC-compatible.

SAV2  Completes the 2-port calibration sequence. OPC-compatible.

SAVC  Completes the transfer of error correction coefficients back into the instrument. OPC-compatible.

These 6 commands (OPC-compatible) store the current instrument state in the indicated internal register.

SAVE1  Register 1.
SAVE2  Register 2.
SAVE3  Register 3.
SAVE4  Register 4.
SAVE5  Register 5.
SAVEREG<i>  Saves to save/recall registers 01 through 31. SAVEREG01 through SAVEREG05 are the same as SAVE1 through SAVE5. OPC-compatible.

SAVT  Completes the TRL/LRM calibration sequence. OPC-compatible.

The 2 following commands define the format for saving files to disk.

SAVUASCII  Selects ASCII format for saving to disk. Conforms to CITIFile specifications.

SAVUBINA  Selects binary format for saving to disk.

SAVEUSEK  Stores the active calibration kit as the user kit.

SCAL[D]  Sets the trace scale factor.

SCAP<FULL|GRAT>  Selects a full plot, or a plot where the graticule is expanded to the plotter’s P1 and P2.

SDEL  During either a list frequency, a limit table edit, or power loss list, deletes the current segment.

SDON  During either a list frequency, a limit table edit, or power loss list, closes a segment after editing.

These 6 commands control the marker searches. The marker searches place the active marker according to the indicated search criteria. The search is continuously updated if tracking is ON (see TRACK):

SEAL  Search left for next occurrence of the target value.

SEAMAX  Search for trace maximum on the current channel.

SEAMIN  Search for trace minimum on the current channel.

SEAOFF  Turns the marker search OFF.

SEAR  Search right for next occurrence of the target value.

SEATARG[D]  Set the search target amplitude.
SED1[D]  During either a frequency, limit, or power loss table edit, selects segment D for editing.

SELL[D]  Selects the learn string revision (LRN) or OUTPLEAS, INPULEAS to be used by the analyzer. The valid parameters are:

0: Defaults to current revision.
201: Revision 8753B 2.01
300: Revision 8753B 3.00
401: Revision 8753C 4.01
402: Revision 8753C 4.02
412: Revision 8753C 4.12
413: Revision 8753C 4.13
500: Revision 8753D 5.00
520: Revision 8753D 5.20
526: Revision 8753D 5.26
534: Revision 8753D 5.34
536: Revision 8753D 5.36
538: Revision 8753D 5.38
540: Revision 8753D 5.40
542: Revision 8753D 5.42
546: Revision 8753D 5.46
548: Revision 8753D 5.48
612: Revision 8753D 6.12

SELMAXPT[D]  Selects the last point number in the range of points that the OUTPDATR command will report. D can range from 0 to the number of points minus 1.

SELMINPT[D]  Selects the first point number in the range of points that the OUTPDATR command will report. D can range from 0 to the number of points minus 1.

SELPT[D]  Selects the point number that the OUTPDATR command will report. D can range from 0 to the number of points minus 1.

SELSER[D]  Selects the segment number to report on for the OUTPSEG and OUTPSEGm commands. D can range from 1 to 18.

SEQ<i>  Selects sequence 1 through 6.

SEQWT[D]  Tells the instrument to wait D seconds during a sequence.

SETBIT[D]  Sets the specified bit (0 to 7) on the GPIO.

SETDATE[$]  Sets the date in the following format: DD MMM YYY, where DD is the day and must be 2 digits, MMM is the month and must be three
alpha characters (JAN, FEB, MAR, APR, MAY, JUN, JUL, AUG, SEP, OCT, NOV, DEC), and YYYY is the year and must be 4 digits.

**SETF**
Set frequency for low pass transform, Option 010.

**SETRTHRU**
Set reference thru.

**SETRREFL**
Set reference reflect.

**SETTIME[$]**
Sets the time in the following format: HH:MM:SS, where HH is the hour, MM is minutes, SS is seconds, and each must be 2 digits.

**SETZ[D]**
Set the characteristic impedance of the measurement system.

**SHOM**
Displays the desired softkey menu during a sequence.

**SING**
Single sweep. OPC-compatible.

**SLID**
Sliding load done.

**SLIL**
Specifies the standard as a sliding load during a standard definition as part of a cal kit modification, as opposed to a fixed or offset load.

**SLIS**
Sliding load set. OPC-compatible.

**SLOPE[D]**
Enter the power slope value.

**SLOPO<ON|OFF>**
Turns the power slope ON and OFF.

**SMS<ON|OFF>**
Selects whether spur avoidance is ON or OFF. Selecting spur avoidance OFF, along with selecting sampler and attenuator offsets OFF (see RAWOFFS<ON|OFF>), saves substantial time at recalls and during frequency changes. Spur avoidance is always coupled between channels: select SMS<OFF> to turn off spur avoidance for both channels. See BASIC programming Example 2E: Take 4 — Error Correction Processed on an External Computer.

**SMIC**
Select Smith chart display format.

The following commands select the marker readout format on a Smith chart:

**SMIMGB**
G+jB (conductance and susceptance).

**SMIMLIN**
Linear magnitude.

**SMIMLOG**
Log magnitude.

**SMIMRI**
Real/imaginary pairs (resistance and reactance).

**SMIMRX**
R+jX.

**SMOAPER[D]**
Sets the smoothing aperture as a percent of the trace.

**SMOOO<ON|OFF>**
Turns smoothing ON and OFF.

**SOFR**
Displays the firmware revision on the screen.

The following 8 commands act as though the indicated soft key was pressed:

**SOFT1**
Softkey 1.

**SOFT2**
Softkey 2.

**SOFT3**
Softkey 3.

**SOFT4**
Softkey 4.

**SOFT5**
Softkey 5.
SOFT6  Softkey 6.
SOFT7  Softkey 7.
SOFT8  Softkey 8.

SOUP<ON|OFF>  Turns the source power ON and OFF.
SPAN[D]  Sets the stimulus span. If a list frequency segment is being edited, sets the span of the segment.

The following commands initiate the SPECIFY CLASS part of modifying a cal kit. After issuing each command, send the analyzer a series of standard numbers to be included in the class. When the class is full, send CLAD; to terminate the specification.

SPECFWDM[I]  Forward match.
SPECFWDT[I]  Forward transmission.
SPECRESP[I]  Response.
SPECRESI[I]  For Resp & Isol, specifies the response standards.
SPECREV[M[I]  Reverse match.
SPECREV[T[I]  Reverse transmission.
SPECS11A[I]  S11A.
SPECS11B[I]  S11B.
SPECS11C[I]  S11C.
SPECS22A[I]  S22A.
SPECS22B[I]  S22B.
SPECS22C[I]  S22C.
SPECTRLL[I]  TRL Line or Match.
SPECTRTL[I]  TRL Thru.
SPECTRRL[I]  TRL Reflect.
SPECTRFM  TRL, Reflect, Forward, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.
SPECTRRM  TRL, Reflect, Reverse, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.
SPECTLFM  TRL, Line, Forward, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.
SPECTLFT  TRL, Line, Forward, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.
SPECTLRM  TRL, Line, Reverse, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.
SPECTLRT  TRL, Line, Reverse, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.
SPECTTFM  TRL, Thru, Forward, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.
SPECTTFT
TRL, Thru, Forward, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.

SPECTTRM
TRL, Thru, Reverse, Match. Compatible with the HP 8753D revisions 5.00 through 5.48.

SPECTTRT
TRL, Thru, Reverse, Trans. Compatible with the HP 8753D revisions 5.00 through 5.48.

SPEG
Displays the specify gate menu. See also DUAC.

SPLD<ON|OFF>
Turns the split display mode ON and OFF.

SRE[D]
Service request enable. A bit set in D enables the corresponding bit in the status byte to generate an SRQ.

SSEG[D]
Selects the desired segment of the frequency list for a list frequency sweep. See also ASEG.

STB?
Outputs the status byte. Same as OUTPSTAT.

The following 7 commands (OPC-compatible) select a standard from a class during a calibration sequence. If a class is requested, as in CLASS11A (S11 1-port cal) the analyzer will do one of two things. If there is only one standard in the class, it will measure that standard automatically. If there are several standards in the class, then one of the following commands must be used to select one of these standards, causing it to be measured.

STANA
Standard listed under softkey 1.

STANB
Standard listed under softkey 2.

STANC
Standard listed under softkey 3.

STAND
Standard listed under softkey 4.

STANE
Standard listed under softkey 5.

STANF
Standard listed under softkey 6.

STANG
Standard listed under softkey 7.

STAR[D]
Enters the start stimulus value. If a list frequency segment is being edited, sets the start of the segment.

STDD
Standard done, terminating a define standard sequence, while modifying a cal kit.

The following 5 commands select the standard “type” after the standard number has been entered during a modify cal kit sequence.

STD|ARBI
Arbitrary impedance.

STD|DELA
Delay/thru.

STD|LOAD
Load.

STD|OPEN
Open.

STD|SHOR
Short.

STOP[D]
Sets the stimulus stop value. If a list frequency segment is being edited, sets the stop of the segment.
These 5 commands store the indicated file on disk. Used with the INTD and EXTD commands to designate the internal or external disk.

**STOR1**
Stores the current instrument state to disk using the file name provided by the preceding TITF1; command.

**STOR2**
Stores the current instrument state to disk using the file name provided by the preceding TITF2; command.

**STOR3**
Stores the current instrument state to disk using the file name provided by the preceding TITF3; command.

**STOR4**
Stores the current instrument state to disk using the file name provided by the preceding TITF4; command.

**STOR5**
Stores the current instrument state to disk using the file name provided by the preceding TITF5; command.

These commands store the instrument state to the indicated sequence to disk. Used with the INTD and EXTD commands to designate the internal or external disk. Requires pass control mode when using the HP-IB port.

**STORSEQ1**
Sequence 1.

**STORSEQ2**
Sequence 2.

**STORSEQ3**
Sequence 3.

**STORSEQ4**
Sequence 4.

**STORSEQ5**
Sequence 5.

**STORSEQ6**
Sequence 6.

**STPSIZE[D]**
While editing a list frequency segment, sets step size.

**SVCO**
Saves display colors.

**SWEA**
Automatically selects the fastest sweep time based on the current analyzer settings for number of points, IF bandwidth, sweep mode, averaging condition and frequency span.

**SWET[D]**
Sets the sweep time.

**SWPSTART**
This OPC-compatible command initiates a sweep and immediately releases the HP-IB bus, allowing the analyzer to initiate data output as soon as the appropriate data is ready. See BASIC programming Example 2E: Take4 — Error Correction Processed on an External Computer.

**SWR**
Selects the SWR display format.

**TAKCS**
 Begins a power meter calibration sweep.

**TAKE4<ON|OFF>**
This command initiates a mode in which every measurement cycle is characterized by sweeping in both the forward and reverse directions and collecting raw data for all four S-parameters. The sweeping can occur when a SWPSTART or SING command is received or when the analyzer is in continuous, number of groups, or external trigger mode. See BASIC programming Example 2E: Take4 — Error Correction Processed on an External Computer.
TAKRS
Take receiver calibration sweep.

TALKLIST
Puts the analyzer in talker listener mode.

TERI[D]
Specifies the terminal impedance of an arbitrary impedance standard during a cal kit modification.

TESS?
Query testset. Returns a one on the standard analyzer. This command is compatible with the HP 8753D.

TIMTRAN<ON|OFF>
Turns the time domain transform ON and OFF. (Option 010). OPC-compatible.

TIMESTAMP<ON|OFF>
Turns on the clock time for prints and plots.

TITF0/I>[S]
Titles the SAVE STATE filename, only in sequence mode.

TINT[D]
Adjusts the tint for the selected display feature.

These commands title the indicated file numbers:

TITF1[S]
File 1.

TITF2[S]
File 2.

TITF3[S]
File 3.

TITF4[S]
File 4.

TITF5[S]
File 5.

TITL[S]
Enters a new display title. A maximum of 50 characters are allowed.

TITP[S]
Titles the plot to disk file.

These commands title the indicated internal register:

TITR1[S]
Register 1.

TITR2[S]
Register 2.

TITR3[S]
Register 3.

TITR4[S]
Register 4.

TITR5[S]
Register 5.

TITREG<1>[S]
Titles save/recall registers 01 through 31. TITREG01 through TITREG05 are the same as TITR1 through TITR5.

TITSEQ<1>[S]
Selects the sequence to be titled. I = 1 to 6.

TITSQ
Provides access to the sequence title functions.

TITMEM
Sends the title string to trace memory.

TITTPMTR
Sends the title string to the power meter's HP-IB address.

TITTPERI
Sends the title string to the peripheral address.

TITTPRIN
Sends the title string to the printer's HP-IB address.

TRACK<ON|OFF>
Turns marker search tracking ON and OFF.

TRAD
Completes the transmission calibration subsequence of a 2-port calibration. OPC-compatible.
**TRAN** Begins the transmission calibration subsequence of a 2-port calibration.

**TRAOP** Begins the transmission calibration subsequence for one path, two port calibration.

**TRAP** Same as S21.

**TRIG** HP-IB trigger.

**TRLL1** Measures TRL Line match for Port 1 during a TRL/LRM 2-port calibration.

**TRLL2** Measures TRL Line match for Port 2 during a TRL/LRM 2-port calibration.

**TRLR1** Measures TRL S11 reflect during a TRL/LRM 2-port calibration.

**TRLR2** Measures TRL S22 reflect during a TRL/LRM 2-port calibration.

**TRIT** Measures TRL thru during a TRL/LRM 2-port calibration.

**TSSWI<ON/OFF>** Same as CSWI.

**TST?** Causes a self test and returns a zero if the test is passed.

**TSTINOWD[D]** Defines 3 bits, D0 through D2, on the test set connector I/O for the channel 1 and channel 2 forward settings. These bits can be set to values of 0 through 7. Be careful that you do not also set a value to ATTP1 and ATTP2 as there is interaction between these commands and they will change the values you have set for D0 through D2 and will couple the channels together. Values for ATTP1 and ATTP2 translate to the following values for D0 through D2:

<table>
<thead>
<tr>
<th>ATTP1/ATTP2</th>
<th>D0 - D2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 dB</td>
<td>7</td>
</tr>
<tr>
<td>16 dB</td>

</tr>
<tr>
<td>70 dB</td>
<td>0</td>
</tr>
</tbody>
</table>
TSTIOREVD  Defines 3 bits, D0 through D2, on the test set connector I/O for the channel 1 and channel 2 reverse settings. These bits can be set to values of 0 through 7. Be careful that you do not also set a value to ATTP1 and ATTP2 as there is interaction between these commands and they will change the values you have set for D0 through D2 and will couple the channels together. Values for ATTP1 and ATTP2 translate to the following values for D0 through D2:

<table>
<thead>
<tr>
<th>ATTP1/ATTP2</th>
<th>D0</th>
<th>D2</th>
</tr>

<tr>
<td>70 dB</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

TSTP<P1|P2>  Selects test port 1 or 2 for non-S-parameter measurements.

These commands set the TTL output and end of sweep pulse:

TTLHPULS  TTL normally low, high pulse at end of sweep.

TTLPULS  TTL normally high, low pulse at end of sweep.

TTLOH  Sets TTL continuously high.

TTLOL  Sets TTL continuously low.

UCONV  Selects up converter for mixer measurements.

UP  Increments the value in the active entry area (up key).

USEPASC  Puts the analyzer in pass control mode.

These commands select the sensor input being used with the HP 438A power meter. For the HP 436A or 437B, the A sensor is always used:

USESENSA  Sensor A.

USESENSB  Sensor B.

VELOFACT[D]  Enters the velocity factor of the transmission medium.

VIEM<ON|OFF>  Displays the measurement trace (ON) or the mixer setup (OFF).

VOFF[D]  Sets the local oscillator frequency for use in frequency offset mode. See also LOFREQ[D].

WAIT  Waits for a clean sweep when used with the OPC command.
WAVD

Selects waveguide electrical delay. (See also COAD.)

WAVE

Specifies a waveguide standard while defining a standard as part of a cal kit modification, as opposed to coaxial.

WIDT<ON|OFF>

Turns the bandwidth search ON and OFF.

WIDV[D]

Enters the widths search parameter.

These 5 commands set the window for the transform (Option 010, time domain):

WINDMAXI

Maximum.

WINDMINI

Minimum.

WINDNORM

Normal.

WINDOW[D]

Enters arbitrary window.

WINDUSEM<ON|OFF>

Turns the trace memory ON as the window shape.

These 8 commands enter new softkey labels into the indicated softkey positions. Initial use of these commands requires previous commands MENUFORM; and MENUOFF;.

WRSK1[$]

Softkey 1.

Softkey 8.
HP BASIC Programming Examples

Introduction

This is an introduction to the remote operation of the HP 8753D Network Analyzer using an external controller. It is a tutorial introduction using BASIC programming examples to demonstrate the remote operation of the network analyzer. The examples used in this chapter are on the “HP 8753D HP BASIC Programming Examples” disk.

The user should be familiar with the operation of the analyzer before attempting to remotely control the analyzer via the Hewlett-Packard Interface Bus (HP-IB). See the *HP 8753D Network Analyzer User's Guide* for analyzer operating information.

The following computers operating with BASIC 6.2 can be used in these examples:

- HP 9000 Series 200/300
- HP 9000 Series 700 with HP BASIC-UX

This document is not intended to teach BASIC programming or to discuss HP-IB theory except at an introductory level.

For more information concerning BASIC, see Table 2-1 for a list of manuals supporting the BASIC revision being used. For more information concerning the Hewlett-Packard Interface Bus, see Table 2-2.

An IBM-compatible personal computer with an HP-IB/GPIB interface card may also be used as an instrument controller. Hewlett-Packard provides a software package, HP BASIC for Windows, that will execute the HP BASIC examples as described in this chapter. Contact your local Hewlett-Packard sales office for further information on this package.
Required Equipment

- Computer ........................................ HP 9000 Series
- BASIC operating system .................................. BASIC 6.2
- HP BASIC Programming Examples disk .......................... 08753-10028
- HP-IB interconnect cables .................................... HP 10833A/B/C/D
- Test device ........................................... such as a 125 MHz bandpass filter

Note

The test device shipped with the instrument is a 10.24 GHz bandpass filter. If you wish to use this device, the frequency ranges of the example programs must be modified accordingly.

Note

The computer must have enough memory to store:
- BASIC 6.2 (4 MBytes of memory is required)
- the required binaries

Upon receipt, make copies of the “Programming Examples” disks. Label them “Programming Examples BACKUP”. These disks will act as reserves in the event of loss or damage to the original disks.

Optional Equipment

See the “Compatible Peripherals” chapter in the HP 8753D Network Analyzer User’s Guide for complete information on the following optional equipment:

- Calibration kits
- Test port return cables
- Plotter
- Printer
- Disk drive

System Setup and HP-IB Verification

This section describes how to:
- Connect the test system.
- Set the test system addresses.
- Set the network analyzer’s control mode.
- Verify the operation of the system’s interface bus (HP-IB).
1. Connect the analyzer to the computer with an HP-IB cable as shown in Figure 2-1.

2. Switch on the computer.

3. Load the BASIC 6.2 operating system.

4. Switch on the analyzer.
   a. To verify the analyzer's address, press:

\[ \text{Local SET ADDRESSES ADDRESS: 8753} \]

The analyzer has only one HP-IB interface, though it occupies two addresses: one for the instrument and one for the display. The display address is equal to the instrument address with the least-significant bit incremented. The display address is automatically set each time the instrument address is set.

The default analyzer addresses are:
- 16 for the instrument
- 17 for the display

**Caution**

Other devices connected to the bus cannot occupy the same address as the analyzer.

The analyzer displays the instrument's address in the upper right section of the display. If the address is not 16, return the address to its default setting (16) by pressing:

\[ \text{[16] [SET]} \]
b. Set the system control mode to either “pass-control” or “talker/listener” mode. These are the only control modes in which the analyzer will accept commands over HP-IB. For more information on control modes, see Chapter 1, “HP-IB Programming and Command Reference.” To set the system control mode, press:

(Local) TALKER/LISTENER

or

(Local) USE PASS CONTROL

5. Check the interface bus by performing a simple command from the computer controller. Type the following command on the controller:

OUTPUT 716;"PRES;" (EXECUTE) or (RETURN)

**Note**
HP 9000 Series 300 computers use the (RETURN) key as both execute and enter. Some other computers may have an (ENTER), (EXECUTE), or (EXEC) key that performs the same function. For reasons of simplicity, the notation (RETURN) is used throughout this chapter.

This command should preset the analyzer. If an instrument preset does not occur, there is a problem. Check all HP-IB addresses and connections. Most HP-IB problems are caused by an incorrect address and faulty/loose HP-IB cables.
HP 8753D Network Analyzer Instrument Control Using BASIC

A remote controller can manipulate the functions of the analyzer by sending commands to the analyzer via the Hewlett-Packard Interface Bus (HP-IB). The commands used are specific to the analyzer. Remote commands executed over the bus take precedence over manual commands executed from the instrument's front panel. Remote commands are executed as soon as they are received by the analyzer. A command only applies to the active channel (except in cases where functions are coupled between channels). Most commands are equivalent to front-panel key presses and softkeys.

Command Structure in BASIC

Consider the BASIC command for setting the analyzer's start frequency to 50 MHz:

```
OUTPUT 716; "STAR 50 MHZ;"
```

The command structure in BASIC has several different elements:

- **the BASIC command statement**
  - OUTPUT - The BASIC data-output statement.

- **the appendage**
  - 716 - The data is directed to interface 7 (HP-IB), and
  - on to the device at address 16 (the analyzer). This
  - appendage is terminated with a semicolon. The next
  - appendage is STAR, the instrument mnemonic for
  - setting the analyzer's start frequency.

- **command data**
  - 50 - a single operand used by the root mnemonic
  - STAR to set the value.

- **command unit**
  - MHZ - the units that the operand is expressed in.

- **command terminator**
  - ; - indicates the end of a command, enters the data,
  - and deactivates the active-entry area.

The "STAR 50 MHZ;" command performs the same function as pressing the following keys on the analyzer's front panel:

```
(START) 50 (MHZ)
```

STAR is the root mnemonic for the start key, 50 is the data, and MHZ are the units. Where possible, the analyzer's root mnemonics are derived from the equivalent key label. Otherwise they are derived from the common name for the function. Chapter 1, "HP-IB Programming and Command Reference," lists all the root mnemonics and all the different units accepted.

The semicolon (;) following MHZ terminates the command within the analyzer. It removes start frequency from the active-entry area, and prepares the analyzer for the next command. If there is a syntax error in a command, the analyzer will ignore the command and look for the next terminator. When it finds the next terminator, it starts processing incoming commands normally. Characters between the syntax error and the next terminator are lost. A line feed also acts as a terminator. The BASIC OUTPUT statement transmits a carriage return/line feed following the data. This can be suppressed by putting a semicolon at the end of the statement.

The OUTPUT 716; statement will transmit all items listed (as long as they are separated by commas or semicolons) including:

- literal information enclosed in quotes,
- numeric variables,
- string variables,
- and arrays.

A carriage return/line feed is transmitted after each item. Again, this can be suppressed by terminating the commands with a semicolon. The analyzer automatically goes into remote...
mode when it receives an OUTPUT command from the controller. When this happens, the
front-panel remote (R) and listen (L) HP-IB status indicators illuminate. In remote mode, the
analyzer ignores any data that is input with the front-panel keys, with the exception of (local).
Pressing (local) returns the analyzer to manual operation, unless the universal HP-IB command
LOCAL LOCKOUT 7 has been issued. There are two ways to exit from a local lockout. Either
issue the LOCAL 7 command from the controller or cycle the line power on the analyzer.

Setting a parameter such as start frequency is just one form of command the analyzer will
accept. It will also accept simple commands that require no operand at all. For example, execute:

OUTPUT 716: "AUTO;"

In response, the analyzer autoscales the active channel. Autoscale only applies to the active
channel, unlike start frequency, which applies to both channels as long as the channels are
stimulus-coupled.

The analyzer will also accept commands that switch various functions ON and OFF. For example, to switch on dual-channel display, execute:

OUTPUT 716: "DUCON;"

DUCON is the analyzer root mnemonic for "dual-channel display on". This causes the analyzer
to display both channels. To go back to single-channel display mode, for example, switch off
dual-channel display, execute:

OUTPUT 716: "DUCOFF;"

The construction of the command starts with the root mnemonic DUC (dual-channel display,)
and ON or OFF is appended to the root to form the entire command.

The analyzer does not distinguish between upper- and lower-case letters. For example, execute:

OUTPUT 716: "auto;"

---

**Note**
The analyzer also has a debug mode to aid in troubleshooting systems.
When the debug mode is ON, the analyzer scrolls incoming HP-IB commands
across the display. To manually activate the debug mode, press (local)
HP-IB DIAG ON. To deactivate the debug mode from the controller, execute:

OUTPUT 716: "DEBUGOFF;"

---

**Command Query**

Suppose the operator has changed the power level from the front panel. The computer can
find the new power level using the analyzer's command-query function. If a question mark is
appended to the root of a command, the analyzer will output the value of that function.

For instance, POWER 7 DB; sets the analyzer's output power to 7 dB, and POWER?; outputs the
current RF output power at the test port to the system controller. For example:

Type SCRATCH and press (RETURN) to clear old programs.
Type EDIT and press (RETURN) to access the edit mode.
Then type in:

```
10 OUTPUT 716;"POWE?;"
20 ENTER 716;Reply
30 DISP Reply
40 END
```

**Running the Program**

The computer will display the preset source-power level in dBm. Change the power level by pressing \([\text{Local Menu}] \text{POWER XX}\) \(\#\). Now run the program again.

When the analyzer receives POWE?, it prepares to transmit the current RF source-power level. The BASIC statement ENTER 716 allows the analyzer to transmit information to the computer by addressing the analyzer to talk. This illuminates the analyzer front-panel talk (T) light. The computer places the data transmitted by the analyzer into the variables listed in the ENTER statement. In this case, the analyzer transmits the output power, which gets placed in the variable Reply.

The ENTER statement takes the stream of binary-data output from the analyzer and reformats it back into numbers and ASCII strings. With the formatting set to its default state, the ENTER statement will format the data into real variables, integers, or ASCII strings, depending on the variable being filled. The variable list must match the data the analyzer has to transmit. If there are not enough variables, data is lost. If there are too many variables for the data available, a BASIC error is generated.

The formatting done by the ENTER statement can be changed. For more information on data formatting, see Chapter 1, "HP-IB Programming and Command Reference" under the section titled "Array Data Formats." The formatting can be deactivated to allow binary transfers of data. Also, the ENTER USING statement can be used to selectively control the formatting.

ON/OFF commands can be also be queried. The reply is a one (1) if the function is active, a zero (0) if it is not active. Similarly, if a command controls a function that is underlined on the analyzer softkey menu when active, querying that command yields a one (1) if the command is underlined, a zero (0) if it is not. For example, press \([\text{Meas}]\). Though there are seven options on the measurement menu, only one is underlined at a time. The underlined option will return a one (1) when queried.

For instance, rewrite line 10 as:

```
10 OUTPUT 716;"DUAC?;"
```

Run the program once and note the result. Then press \([\text{Local DISPLAY DUAL CHAN}]\) to toggle the display mode, and run the program again.

Another example is to rewrite line 10 as:

```
10 OUTPUT 716;"PHAS?;"
```

In this case, the program will display a one (1) if phase is currently being displayed. Since the command only applies to the active channel, the response to the PHAS? inquiry depends on which channel is active.
Operation Complete

Occasionally, there is a need to query the analyzer as to when certain analyzer operations have completed. For instance, a program should not have the operator connect the next calibration standard while the analyzer is still measuring the current one. To provide such information, the analyzer has an “operation complete” reporting mechanism, or OPC command, that will indicate when certain key commands have completed operation. The mechanism is activated by sending either OPC or OPC? immediately before an OPC-compatible command. When the command completes execution, bit 0 of the event-status register will be set. If OPC was queried with OPC?, the analyzer will also output a one (1) when the command completes execution.

As an example, type SCRATCH and press (RETURN).

Type EDIT and press (RETURN).

Type in the following program:

```
10 OUTPUT 716;"SWET 3 S;OPC?;SING;"  Set the sweep time to 3 seconds and OPC a single sweep.
20 DISP "Sweeping"
30 ENTER 716;Reply

40 DISP "DONE"
50 END
```

Running the Program

Running this program causes the computer to display the sweeping message as the instrument executes the sweep. The computer will display DONE just as the instrument goes into hold. When DONE appears, the program could then continue on, being assured that there is a valid data trace in the instrument.

Preparing for Remote (HP-IB) Control

At the beginning of a program, the analyzer is taken from an unknown state and brought under remote control. This is done with an abort/clear sequence. ABORT 7 is used to halt bus activity and return control to the computer. CLEAR 716 will then prepare the analyzer to receive commands by:

- clearing syntax errors
- clearing the input-command buffer
- clearing any messages waiting to be output

The abort/clear sequence readies the analyzer to receive HP-IB commands. The next step involves programming a known state into the analyzer. The most convenient way to do this is to preset the analyzer by sending the PRES(preset) command. If preset cannot be used, the status-reporting mechanism may be employed. When using the status-reporting register, CLES (Clear Status) can be transmitted to the analyzer to clear all of the status-reporting registers and their enables.

Type SCRATCH and press (RETURN).
Type EDIT and press (RETURN). Type in the following program:

```
10 ABORT 7
20 CLEAR 716
30 OUTPUT 716;"PRES;"
40 END
```

*This halts all bus action and gives active control to the computer.*

*This clears all HP-IB errors, resets the HP-IB interface, and clears the syntax errors. It does not affect the status-reporting system.*

*Presents the instrument. This clears the status-reporting system, as well as resets all of the front-panel settings, except for the HP-IB mode and the HP-IB addresses.*

*Running this program brings the analyzer to a known state, ready to respond to HP-IB control.*

The analyzer will not respond to HP-IB commands unless the remote line is asserted. When the remote line is asserted, the analyzer is addressed to listen for commands from the controller. In remote mode, all the front-panel keys are disabled (with the exception of \( \text{local} \) and the line-power switch). \( \text{ABORT 7} \) asserts the remote line, which remains asserted until a \( \text{LOCAL 7} \) statement is executed. Another way to assert the remote line is to execute:

```
REMOTE 716
```

This statement asserts the analyzer's remote-operation mode and addresses the analyzer to listen for commands from the controller. Press any front-panel key except \( \text{local} \). Note that none of the front-panel keys will respond until \( \text{local} \) has been pressed.

\( \text{local} \) can also be disabled with the sequence:

```
REMOTE 716
LOCAL LOCKOUT 7
```

After executing the code above, none of front-panel keys will respond. The analyzer can be returned to local mode temporarily with:

```
LOCAL 716
```

As soon as the analyzer is addressed to listen, it goes back into local-lockout mode. The only way to clear the local-lockout mode, aside from cycling line power, is to execute:

```
LOCAL 7
```

This command un-asserts the remote line on the interface. This puts the instrument into local mode and clears the local-lockout command. Return the instrument to remote mode by pressing:

```
\( \text{local} \) TALKER/LISTENER
```

or

```
\( \text{local} \) USE PASS CONTROL
```
I/O Paths

One of the features of HP BASIC is the use of input/output paths. The instrument may be addressed directly by the instrument’s device number as shown in the previous examples. However, a more sophisticated approach is to declare I/O paths such as: ASSIGN @Iw TO 716. Assigning an I/O path builds a look-up table in the computer’s memory that contains the device-address codes and several other parameters. It is easy to quickly change addresses throughout the entire program at one location. I/O operation is more efficient because it uses a table, in place of calculating or searching for values related to I/O. In the more elaborate examples where file I/O is discussed, the look-up table contains all the information about the file. Execution time is decreased, because the computer no longer has to calculate a device’s address each time that device is addressed.

For example:
Type SCRATCH and press (RETURN).
Type EDIT and press (RETURN).
Type in the following program:

```
10 ASSIGN @Iwa TO 716  \ Assigns the analyzer to ADDRESS 716.
20 OUTPUT @Iwa;"STAR 50 MHZ;"  \ Sets the analyzer’s start frequency to 50 MHz.
```

**Note**
The use of I/O paths in binary-format transfers allows the user to quickly distinguish the type of transfer taking place. I/O paths are used throughout the examples and are highly recommended for use in device input/output.
Measurement Process

This section explains how to organize instrument commands into a measurement sequence. A typical measurement sequence consists of the following steps:

1. setting up the instrument
2. calibrating the test setup
3. connecting the device under test
4. taking the measurement data
5. post-processing the measurement data
6. transferring the measurement data

Step 1. Setting Up the Instrument

Define the measurement by setting all of the basic measurement parameters. These include:

- the sweep type
- the frequency span
- the sweep time
- the number of points (in the data trace)
- the RF power level
- the type of measurement
- the IF averaging
- the IF bandwidth

You can quickly set up an entire instrument state, using the save/recall registers and the learn string. The learn string is a summary of the instrument state compacted into a string that the computer reads and retransmits to the analyzer. See “Example 5A: Using the Learn String.”

Step 2. Calibrating the Test Setup

After you have defined an instrument state, you should perform a measurement calibration. Although it is not required, a measurement calibration improves the accuracy of your measurement data.

The following list describes several methods to calibrate the analyzer:

- Stop the program and perform a calibration from the analyzer’s front panel.
- Use the computer to guide you through the calibration, as discussed in:
  - “Example 2A: S_{11} 1-Port Measurement Calibration.”
  - “Example 2B: Full 2-Port Measurement Calibration.”
  - “Example 2C: Adapter Removal Calibration.”
  - “Example 2D: Using Raw Data to Create a Calibration (Simmeal).”
  - “Example 2E: Take4 — Error Correction Processed on an External PC.”
- Transfer the calibration data from a previous calibration back into the analyzer, as discussed in “Example 5C: Saving and Restoring the Analyzer Instrument State.”
Step 3. Connecting the Device under Test
After you connect your test device, you can use the computer to speed up any necessary device adjustments such as limit testing, bandwidth searches, and trace statistics.

Step 4. Taking the Measurement Data
Measure the device response and set the analyzer to hold the data. This captures the data on the analyzer display.

By using the single-sweep command (SING), you can insure a valid sweep. When you use this command, the analyzer completes all stimulus changes before starting the sweep, and does not release the HP-IB hold state until it has displayed the formatted trace. Then when the analyzer completes the sweep, the instrument is put into hold mode, freezing the data. Because single sweep is OPC-compatible, it is easy to determine when the sweep has been completed.

The number-of-groups command (NUMGn) triggers multiple sweeps. It is designed to work the same as single-sweep command. NUMGn is useful for making a measurement with an averaging factor n (n can be 1 to 999). Both the single-sweep and number-of-groups commands restart averaging.

Step 5. Post-Processing the Measurement Data
Figure 1-4 shows the process functions used to affect the data after you have made an error-corrected measurement. These process functions have parameters that can be adjusted to manipulate the error-corrected data prior to formatting. They do not affect the analyzer’s data gathering. The most useful functions are trace statistics, marker searches, electrical-delay offset, time domain, and gating.

After performing and activating a full 2-port measurement calibration, any of the four S-parameters may be viewed without taking a new sweep.

Step 6. Transferring the Measurement Data
Read your measurement results. All the data-output commands are designed to insure that the data transmitted reflects the current state of the instrument.
BASIC Programming Examples

The following sample programs provide the user with factory-tested solutions for several remotely-controlled analyzer processes. The programs can be used in their present state or modified to suit specific needs. The programs discussed in this section can be found on the "HP 8753D HP BASIC Programming Examples" disk received with the analyzer.

- Example 1: Measurement Setup
  - Example 1A: Setting Parameters
  - Example 1B: Verifying Parameters
- Example 2: Measurement Calibration
  - Example 2A: S11 1-Port Measurement Calibration
  - Example 2B: Full 2-Port Measurement Calibration
  - Example 2C: Adapter Removal Calibration
  - Example 2D: Using Raw Data to Create a Calibration (Simmeal)
  - Example 2E: Take4 — Error Correction Processed on an External PC
- Example 3: Measurement Data Transfer
  - Example 3A: Data Transfer Using Markers
  - Example 3B: Data Transfer Using FORM 4 (ASCII Transfer)
  - Example 3C: Data Transfer Using Floating-Point Numbers
  - Example 3D: Data Transfer Using Frequency—Array Information
  - Example 3E: Data Transfer Using FORM 1 (Internal Binary Format)
- Example 4: Measurement Process Synchronization
  - Example 4A: Using the Error Queue
  - Example 4B: Generating Interrupts
  - Example 4C: Power Meter Calibration
- Example 5: Network Analyzer System Setups
  - Example 5A: Using the Learn String
  - Example 5B: Reading Calibration Data
  - Example 5C: Saving and Restoring the Analyzer Instrument State
- Example 6: Limit-Line Testing
  - Example 6A: Setting Up a List-Frequency Sweep
  - Example 6B: Selecting a Single Segment from a Table of Segments
  - Example 6C: Setting Up Limit Lines
  - Example 6D: Performing PASS/FAIL Tests While Tuning
- Example 7: Report Generation
  - Example 7A1: Operation Using Talker/Listener Mode
  - Example 7A2: Controlling Peripherals Using Pass-Control Mode
  - Example 7A3: Printing with the Serial Port
Example 7B: Plotting to a File and Transferring the File Data to a Plotter

- Utilizing PC-Graphics Applications Using the Plot File

Example 7C: Reading ASCII Disk Files to the Instrument Controller’s Disk File

Example 8: Mixer Measurements

Example 8A: Comparison of Two Mixers — Group Delay, Amplitude or Phase

Program Information

The following information is provided for every example program included on the “Programming Examples” disk:

- A program description
- An outline of the program’s processing sequence
- A step-by-step instrument-command-level tutorial explanation of the program including:
  - The command mnemonic and command name for the HP-IB instrument command used in the program.
  - An explanation of the operations and affects of the HP-IB instrument commands used in the program.

Note: The HP BASIC programming code for each of these examples is contained in “HP BASIC Programming Examples.”

Analyzer Features Helpful in Developing Programming Routines

Analyzer-Debug Mode

The analyzer-debug mode aids you in developing programming routines. The analyzer displays the commands being received. If a syntax error occurs, the analyzer displays the last buffer and points to the first character in the command line that it could not understand.

You can enable this mode from the front panel by pressing (local) HP-IB DIAG ON. The debug mode remains activated until you preset the analyzer or deactivate the mode. You can also enable this mode over the HP-IB using the DEBUON; command and disable the debug mode using the DEBUOFF; command.

User-Controllable Sweep

There are three important advantages to using the single-sweep mode:

1. The user can initiate the sweep.
2. The user can determine when the sweep has completed.
3. The user can be confident that the trace data has been derived from a valid sweep.

Execute the command string OPC?;SING; to place the analyzer in single-sweep mode and trigger a sweep. Once the sweep is complete, the analyzer returns an ASCII character one (1) to indicate the completion of the sweep.

Note: The measurement cycle and the data acquisition cycle must always be synchronized. The analyzer must complete a measurement sweep for the data to be valid.
Example 1: Measurement Setup

The programs included in Example 1 provide the user the option to perform instrument-setup functions for the analyzer from a remote controller. Example 1A is a program designed to setup the analyzer's measurement parameters. Example 1B is a program designed to verify the measurement parameters.

Example 1A: Setting Parameters

| Note | This program is stored as EXAMPA on the “Programming Examples” disk received with the network analyzer. |

In general, the procedure for setting up measurements on the network analyzer via HP-IB follows the same sequence as if the setup was performed manually. There is no required order, as long as the desired frequency range, number of points, and power level are set prior to performing the calibration first, and the measurement second.

This example sets the following parameters:

- reflection log magnitude on channel 1
- reflection phase on channel 2
- dual channel display mode
- frequency range from 100 MHz to 500 MHz

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The analyzer is adjusted to measure return loss (S11) on channel 1 and display it in log magnitude.
- The analyzer is adjusted to measure return loss (S11) on channel 2 and display the phase.
- The dual-channel display mode is activated.
- The system operator is prompted to enter the frequency range of the measurement.
- The displays are autoscaled.
- The analyzer is released from remote control and the program ends.
The program is written as follows:

```
10 ! This program selects the S-parameter to be measured, the display
20 ! format and then sets the specified start and stop frequencies.
30 ! The analyzer display is then autoscaled.
40 !
50 ! EXAMP1A
60 !
70 ASSIGN @Nwa T0 716 ! Assign an I/O path for the analyzer
80 !
90 CLEAR SCREEN
100 ! Initialize the system
110 ABORT 7 ! Generate an IFC (Interface Clear)
120 CLEAR @Nwa ! SDC (Selected Device Clear) analyzer
130 OUTPUT @Nwa;"0PC?;PRES;" ! Preset the analyzer and wait
140 ENTER @Nwa;Reply ! Read in the 1 returned
150 !
160 ! Set up measurement and display
170 OUTPUT @Nwa;"CHAN1;" ! Channel 1
180 OUTPUT @Nwa;"S11;" ! Return Loss measurement
190 OUTPUT @Nwa;"LOGM;" ! Log magnitude display
200 !
210 OUTPUT @Nwa;"CHAN2;" ! Channel 2
220 OUTPUT @Nwa;"S11;" ! Return Loss measurement
230 OUTPUT @Nwa;"PHAS;" ! Phase display
240 !
250 OUTPUT @Nwa;"DUACON;" ! Dual channel display
260 !
270 ! Request start and stop frequency
280 INPUT "ENTER START FREQUENCY (MHz):",F_start
290 INPUT "ENTER STOP FREQUENCY (MHz):",F_stop
300 !
310 ! Program the analyzer settings
320 OUTPUT @Nwa;"STAR";F_start;"MHZ;" ! Set the start frequency
330 OUTPUT @Nwa;"STOP";F_stop;"MHZ;" ! Set the stop frequency
340 !
350 ! Autoscale the displays
360 OUTPUT @Nwa;"CHAN1;AUTO;" ! Autoscale channel 1 display
370 OUTPUT @Nwa;"CHAN2;AUTO;" ! Autoscale channel 2 display
380 !
390 OUTPUT @Nwa;"0PC?;WAIT;" ! Wait for the analyzer to finish
400 ENTER @Nwa;Reply ! Read the 1 when complete
410 LOCAL @Nwa ! Release HP-IB control
420 END
```

**Running the Program**

The analyzer is initialized and the operator is queried for the measurement's start and stop frequencies. The analyzer is setup to display the $S_{11}$ reflection measurement as a function of log magnitude and phase over the selected frequency range. The displays are autoscaled and the program ends.
Example 1B: Verifying Parameters

Note This program is stored as EXAMP1B on the “Programming Examples” disk received with the network analyzer.

This example shows how to read analyzer settings into your controller. Chapter 1, “HP-IB Programming and Command Reference,” contains additional information on the command formats and operations. Appending a “?” to a command that sets an analyzer parameter will return the value of that setting. Parameters that are set as ON or OFF when queried will return a zero (0) if OFF or a one (1) if active. Parameters are returned in ASCII format, FORM 4. This format is varying in length from 1 to 24 characters-per-value. In the case of marker or other multiple responses, the values are separated by commas.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The number of points in the trace is queried and dumped to a printer.
- The start frequency is queried and output to a printer.
- The averaging is queried and output to a printer.
- The analyzer is released from remote control and the program ends.

The program is written as follows:

```
10 ! This program performs some example queries of network analyzer
20 ! settings. The number of points in a trace, the start frequency
30 ! and if averaging is turned on, are determined and displayed.
40 !
50 ! EXAMP1B
60 !
70 ASSIGN @Nwa T0 716 ! Assign an I/O path for the analyzer
80 !
90 CLEAR SCREEN
100 ! Initialize the system
110 ABORT 7 ! Generate an IFC (Interface Clear)
120 CLEAR @Nwa ! SDC (Selected Device Clear)
130 OUTPUT @Nwa;"OPC?;PRES;" ! Preset the analyzer and wait
140 ENTER @Nwa;Reply ! Read in the i returned
150 !
160 ! Query network analyzer parameters
170 OUTPUT @Nwa;"POIN?;" ! Read in the default trace length
180 ENTER @Nwa;Num_points
190 PRINT "Number of points ";Num_points
200 PRINT
210 !
220 OUTPUT @Nwa;"STAR?;" ! Read in the start frequency
230 ENTER @Nwa;Start_f
240 PRINT "Start Frequency ";Start_f
250 PRINT
260 !
270 OUTPUT @Nwa;"AVER0?;" ! Averaging on?
280 ENTER @Nwa;Flag
```
290 PRINT "Flag =";Flag;" ";
300 IF Flag=1 THEN ! Test flag and print analyzer state
310 PRINT "Averaging ON"
320 ELSE
330 PRINT "Averaging OFF"
340 END IF
350 !
360 OUTPUT @Nwa;"OPC?;WAIT;" ! Wait for the analyzer to finish
370 ENTER @Nwa;Reply ! Read the 1 when complete
380 LOCAL @Nwa ! Release HP-IB control
390 END

Running the Program

The analyzer is preset. The preset values are returned and printed out for: the number of points, the start frequency, and the state of the averaging function. The analyzer is released from remote control and the program ends.
Example 2: Measurement Calibration

This section shows you how to coordinate a measurement calibration over HP-IB. You can use the following sequence for performing either a manual measurement calibration, or a remote measurement calibration via HP-IB:

1. Select the calibration type.
2. Measure the calibration standards.
3. Declare the calibration done.

The actual sequence depends on the calibration kit and changes slightly for 2-port calibrations, which are divided into three calibration sub-sequences. The following examples are included:

- Example 2A is a program designed to perform an $S_{11}$ 1-port measurement calibration.
- Example 2B is a program designed to perform a full 2-port measurement calibration.
- Example 2C is a program designed to accurately measure a “non-insertable” 2-port device, using adapter removal.
- Example 2D is a program designed to use raw data to create a calibration, sometimes called Simcal.
- Example 2E is a program designed to offload the calculation of the 2-port error corrected data to an external computer.

Calibration Kits

The calibration kit tells the analyzer what standards to expect at each step of the calibration. The set of standards associated with a given calibration is termed a “class.” For example, measuring the short during an $S_{11}$ 1-port measurement calibration is one calibration step. All of the shorts that can be used for this calibration step make up the class, which is called class $S11B$. For the 7-mm and the 3.5-mm cal kits, class $S11B$ uses only one standard. For type-N cal kits, class $S11B$ contains two standards: male and female shorts.

When doing an $S_{11}$ 1-port measurement calibration using a 7- or 3.5-mm calibration kit, selecting SHORT automatically measures the short because the class contains only one standard. When doing the same calibration in type-N, selecting SHORT brings up a second menu, allowing the operator to select which standard in the class is to be measured. The sex listed refers to the test port: if the test port is female, then the operator selects the female short option. Once the standard has been selected and measured, the DONE key must be pressed to exit the class.

Doing an $S_{11}$ 1-port measurement calibration over HP-IB is very similar. When using a 7- or 3.5-mm calibration kit, sending CLASS11B will automatically measure the short. In type-N, sending CLASS11B brings up the menu with the male and female short options. To select a standard, use STANA or STANB. The STAN command is appended with the letters A through G, corresponding to the standards listed under softkeys 1 through 7, softkey 1 being the topmost softkey.

The STAN command is OPC-compatible. A command that calls a class is only OPC-compatible if that class has only one standard in it. If there is more than one standard in a class, the command that calls the class brings up another menu, and there is no need to query it. DONE; must be sent to exit the class.
Example 2A: S11 1-Port Calibration

Note  This program is stored as EXAMP2A on the “Programming Examples” disk received with the network analyzer.

The following program performs an S11 1-port calibration, using either the HP 85031B 7-mm calibration kit or the HP 85033D 3.5-mm calibration kit. If you wish to use a different calibration kit, modify the example program accordingly. This program simplifies the calibration by providing explicit directions on the analyzer display while allowing the user to run the program from the controller keyboard. More information on selecting calibration standards can be found in the Optimizing Measurement Results chapter of the HP 8753D/Option 011 Network Analyzer User’s Guide.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The appropriate calibration kit is selected.
- The softkey menu is deactivated.
- The S11-calibration sequence is run.
- The S11-calibration data is saved.
- The softkey menu is activated.
- The analyzer is released from remote control and the program ends.
The program is written as follows:

1  ! This program guides the operator through a 1-port calibration.
2  ! The operator must choose either the HP 85031B 7 mm calibration kit
3  ! or the HP 85033D 3.5 mm calibration kit.
4  ! The routine Waitforkey displays a message on the instrument’s
5  ! display and the console, to prompt the operator to connect the
6  ! calibration standard. Once the standard is connected, the
7  ! ENTER key on the computer keyboard is pressed to continue.
8  !
9  ! EXAMP2A
10  
11  ASSIGN @Nwa T0 716  ! Assign an I/O path for the analyzer

Running the Program

Note This program does not modify the instrument state in any way. Before running
the program, set up the desired instrument state.

The program assumes that the test ports have either a 7-mm or 3.5-mm interface or an adapter
set using either a 7-mm or 3.5-mm interface. The prompts appear just above the message line
on the analyzer display. Pressing [ENTER] on the controller keyboard continues the program and
measures the standard. The program will display a message when the measurement calibration
is complete.
Example 2B: Full 2-Port Measurement Calibration

Note

This program is stored as EXAMP2B on the "Programming Examples" disk received with the network analyzer.

The following example program performs a full 2-port measurement calibration using either the HP 85031B 7-mm calibration kit or the HP 85033D 3.5-mm calibration kit. If you wish to use a different calibration kit, modify the example program accordingly. A full 2-port calibration removes both the forward- and reverse-error terms so all four S-parameters of the device under test can be measured. PORT 1 is a female test port and PORT 2 is a male test port.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The appropriate calibration kit is selected.
- The softkey menu is deactivated.
- The 2-port calibration sequence is run.
- The operator is prompted to choose or skip the isolation calibration.
- The softkey menu is activated.
- The analyzer is released from remote control and the program ends.

The program is written as follows:

```
1 ! This program guides the operator through a full 2-port calibration.
2 ! The operator must choose either the HP 85031B 7 mm calibration kit
3 ! or the HP 85033D 3.5 mm calibration kit.
4 ! The routine Waitforkey displays a message on the instrument’s
5 ! display and the console to prompt the operator to connect the
6 ! calibration standard. Once the standard is connected, the
7 ! ENTER key on the computer keyboard is pressed to continue.

HP BASIC Programming Examples  2:25
Running the Program

**Note** Before running the program, set the desired instrument state. This program does not modify the instrument state in any way.

Run the program and connect the standards as prompted. After the standard is connected, press [ENTER] on the controller keyboard to continue the program.

The program assumes that the test ports have either a 7-mm or 3.5-mm interface or an adapter set using either a 7-mm or 3.5-mm interface. The prompts appear just above the message line on the analyzer display. After the prompt is displayed, pressing [ENTER] on the computer console continues the program and measures the standard. The operator has the option of omitting the isolation calibration. If the isolation calibration is performed, averaging is automatically employed to insure a good calibration. The program will display a message when the measurement calibration is complete.
Example 2C: Adapter Removal Calibration

Note  This program is stored as EXAMP2C on the “Programming Examples” disk received with the network analyzer.

This program shows how to accurately measure a “non-insertable” 2-port device. A device is termed “non-insertable” if its connectors do not match those of the analyzer front panel. More information on the adapter removal technique can be found in the “Optimizing Measurement Results” chapter of the HP 8753D Network Analyzer User’s Guide.

The following is an outline of the program’s processing sequence:

■ An I/O path is assigned for the analyzer.
■ The system is initialized.
■ The internal disk is selected as the active storage device.
■ The system operator is prompted for the name of the instrument state file which has a 2-port calibration performed for Port 1’s connector.
■ The calibration arrays for Port 1 are recalled from the corresponding disk file.
■ The system operator is prompted for the known electrical delay value of the adapter.
■ The new calibration coefficients, with the effects of the adapter removed, are computed by the analyzer using the adapter delay in conjunction with the calibration arrays for both ports.
■ The analyzer is released from remote control and the program ends.

The program is written as follows:

1 ! This program demonstrates how to do adapter removal over HP-IB.
2 !
3 ! EXAMP2C
4 !
5 REAL Delay ! Adapter electrical delay in picoseconds

61 LOCAL 7 ! Release HP-IB control
62 DISP "Program completed"
63 END

Running the Program

The analyzer is initialized and the internal disk drive is selected. The operator is queried for the name of the instrument state file having a 2-port calibration performed for Port 1's connector. The calibration arrays for Port 1 are recalled from the corresponding disk file. The system operator is prompted for the name of the instrument state file having a 2-port calibration performed for Port 2's connector. The calibration arrays for Port 2 are recalled from the corresponding disk file. The system operator is prompted for the known electrical delay of the adapter and this value is written to the analyzer. The calibration coefficients with adapter effects removed are computed and the program ends.
Example 2D: Using Raw Data to Create a Calibration (Simmcal)

**Note**  
This program is stored as EXAMP2D on the “Programming Examples” disk received with the network analyzer.

This program simulates a full 2-port cal by measuring the raw data for each “standard” and then loading it later into the appropriate arrays. The program can be adapted to create additional calibrations using the same arrays. It uses the HP85031B 7-mm cal kit.

**Caution**  
This feature is not currently supported with TRL calibrations.

The following is an outline of the programs’ processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initiated.
- The number of points is set to correspond to the size of the dimensioned memory arrays and ASCII data format is selected.
- The 7-mm calibration kit is selected, sweep time is set to 1 second, and the analyzer is placed into hold mode.
- S11 measurement is selected for gathering the forward reflection standards.
- The system operator is prompted to connect each of the three standards, one at a time.
- Following each prompt, a single sweep is taken and the raw measured data for that standard is read from the analyzer into a corresponding memory array in the controller.
- S22 measurement is selected for gathering the reverse reflection standards.
- The system operator is prompted in the same manner as before and the raw data for the three standards is measured and stored away as before.
- The system operator is prompted to make the thru connection between Port 1 and Port 2.
- S21 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to forward transmission.
- S11 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to forward thru match.
- S12 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to reverse transmission.
- S22 measurement is selected, a single sweep is taken and the raw data is read into an array corresponding to reverse thru match.
- The analyzer begins the normal 2-port calibration procedure, but with the default beep turned off.
- A single sweep is taken for the measurement of each standard to provide “dummy” data, which is immediately replaced with the previously measured raw data from the array corresponding to that measurement.
- The analyzer uses the raw data to compute the error coefficients and is placed back into continuous sweep mode.
- The analyzer is released from remote control and the program ends.
The program is written as follows:

1   ! This program simulates a full 2-port cal by first getting the
2   ! raw data for each "standard" and then loading it into the
3   ! appropriate arrays later. For simplicity, this is done with
4   ! ASCII format, 51 points, and the default calibration kit in the
5   ! 8753D (7mm). This also simplifies the input of the standards
6   ! because there is only one standard associated with a particular
7   ! class with the default 7mm cal kit. See notes below for how to
8   ! handle multiple standards for a particular class.
9   !
10  EXAMP2D
11  !
12  ! Allocate the arrays. The numbers correspond to the subsequent
13  ! cal coefficient array that will be written.

260 END

Running the Program

The system is initialized, the number of points is set to 51, and the 7-mm calibration kit is
selected. Sweep time is set to 1 second and the analyzer is placed into hold mode.

The $S_{11}$ measurement is selected and the system operator is prompted to connect each of the
three forward reflection standards, one at a time. Following each prompt, a single sweep is
taken, which concludes with a beep from the external controller.

The $S_{22}$ measurement is selected for gathering the reverse reflection standards. The system
operator is prompted in the same manner as before and the three standards are measured as
before.
The system operator is prompted to make the thru connection between Port 1 and Port 2. A single sweep is taken for each of the four S-parameters, each concluding with a beep.

The analyzer begins the normal 2-port calibration procedure, but with the default beep turned off. A single sweep is taken for each measurement of each standard, providing "dummy" data which is immediately replaced with the data from the array corresponding to that measurement. The analyzer computes the error correction coefficients and is placed back into continuous sweep mode. The default beep is re-enabled and the program ends.
Example 2E: Take4 — Error Correction Processed on an External PC

Note This program is stored as EXAMP2E on the “Programming Examples” disk received with the network analyzer.

Overview

Take4 mode offloads the error correction process to an external PC in order to increase throughput on the analyzer.

When using the analyzer with error correction turned off, it will only sweep in one direction, collecting data for the parameter selected under the MEAS key. To emulate the error correction process in an external computer, you collect the raw data for each of the four S-parameters.

Take4 initiates a mode in which every measurement cycle is characterized by sweeping in both the forward and reverse directions and collecting raw data for all four S-parameters. Using previously extracted calibration arrays, you can then extract the raw data (or the pre-raw data, as explained later in this section) for the S-parameters and perform the error correction in an external computer. This process can be done in less time than a single corrected parameter can be measured and transferred using the normal instrument error correction and data transfer (see Table 2-3).

Note This mode is intended for remote use only. Any attempt to change the measured parameter or any attempt to apply a calibration will turn off the Take4 mode. The displayed trace data is always uncorrected S11, regardless of what the display may indicate.

Using the Take4 Mode

Using the Take4 mode requires the following steps:

Manual steps:

1. Set up the measurement state.
2. Turn off raw offsets by selecting SYSTEM, CONFIGURE MENU, RAW OFFSET OFF. This selection achieves two things:
   - Eliminates attenuator offsets and sampler hardware offsets from the cal arrays, which are generated in the 2-port error correction. This makes the cal arrays and the eventual OUTPARE arrays compatible, both using pre-raw data (see Fig 1-3).
   - Eliminates sampler correction, a frequency response correction that is normally contained in pre-raw data. This is done because sampler correction is not needed for data that will be fully corrected, and because instrument states recall faster without it. To realize this efficiency, you must also disable spur avoidance (see next step).
3. Optional step: Turn off spur avoidance by selecting SYSTEM, CONFIGURE MENU, SPUR AVOID OFF. Spur avoidance creates a table of values as part of the sampler offset table. The creation of this table takes considerable time during a recall of an instrument state. Turning off spur avoidance will save time during frequency changes and instrument state recalls.
4. Perform a 2-port error correction and save it to a register.
5. Connect the device under test (DUT).

The instrument is now configured for the program to read the correction arrays and apply the Take4 mode.
Programming steps:

6. Extract the twelve calibration arrays using the commands OUTPCALC[01-12].
7. Enable Take4 mode using the command TAKE4ON.
8. Take a sweep and extract the four pre-raw or raw arrays.
   - To extract pre-raw data arrays (see previous discussion on raw offsets), you can use the commands SWPSTART (initiate a single sweep) with OUTPPRE[1-4]. These commands are more efficient than SING and OUTPRAW[1-4] because the analyzer will respond to OUTPPRE1 and OUTPPRE2 as soon as the forward sweep is done and transfer the data during the reverse sweep. With SING, the HP-IB bus is held off until the entire sweep is complete.
   - To extract raw data arrays, you can use the commands SING (initiate a single sweep) with OUTPRAW[1-4], or the slightly faster OUTPRAW[1-4]. If the cal arrays were created using RAW OFFSET ON, you should use this method so that your measurement data is compatible with the calibration data.

9. Apply the calibration arrays (see Table 1-8) to either the pre-raw or raw data as described in programming example 2G and in the User’s Guide (see figure titled “Full 2-Port Error Model” in chapter 6).

### Programming Example

Basic programming example 2G is the complete execution of a two port error correction offloaded to an external PC.

The following is an outline of the programs’ processing sequence:

- An I/O path is assigned for the analyzer. Binary mode is used for data transfers in order to get the fastest response.
- The system is initialized.
- The state of raw offsets is queried and turned off if they had been on.
- The analyzer is placed into local mode and the system operator is prompted to set up a 2-port calibration before continuing.
- The calibration coefficients are read from the analyzer into memory arrays.
- The calibration is turned off and the analyzer is placed into TAKE4 mode and HOLD mode.
- The operator is prompted to connect the DUT and select which S-parameter to send back to the analyzer.
The currently displayed data is saved to the analyzer’s internal memory to initialize the memory array.

The analyzer is set up to display memory only and the default beep is turned off.

The operator is prompted to press any key to terminate the program.

A sweep is initiated and the main loop of the program begins.

After the sweep concludes, the four pre-raw S-parameters are read from the analyzer into an array in the computer.

The error-corrected (calibrated) S-parameters are calculated using the pre-raw data and calibration coefficients.

The calibrated data for the S-parameter selected earlier is sent into the analyzer and saved to the analyzer’s internal memory.

A new sweep is initiated and the loop repeats if there has been no keyboard activity.

Upon exit of the loop, the analyzer is set up to display the active measurement trace.

The analyzer’s internal calibration is turned back on and continuous sweep mode is resumed.

The analyzer is released from remote control and the program ends.

The program is written as follows:

```plaintext
1    ! This program demonstrates the TAKE4 mode.
2    ! The program first asks the user to set up the instrument
3    ! with a 2-port calibration. The subroutine "Read_Cal_co"
4    ! is used to read the 12 term error correction arrays into
5    ! a (N x 12) 2-dimension array (N = number of points). This will
6    ! be used in the "Calc_2_port" subroutine. The program turns off
7    ! error correction, puts the analyzer in hold, turns on TAKE4
8    ! mode, and starts a sweep. The subroutine "Read_4_raw" reads in
9    ! the uncorrected data. The subroutine "Calc_2_port" calculates
10    ! the error correction and returns the corrected arrays.
11    ! The corrected S-parameter is re-input to the analyzer, stored
12    ! in the memory trace and displayed in memory for a visual
13    ! indication of the take4 function.

236 END

Running the Program

The analyzer is initialized and raw offsets are turned off. After the analyzer is placed in local mode, the operator is prompted to set up a 2-port calibration before continuing. The resulting calibration coefficients are read from the analyzer into memory arrays.

Next, the calibration is turned off and the analyzer is placed into TAKE4 mode and HOLD mode. After being prompted to connect the DUT, the operator selects which S-parameter to send back to the analyzer. The currently displayed data is saved to the analyzer’s internal memory and the analyzer is set up to display memory only. The operator is prompted to press any key to terminate the program, a sweep is initiated and the main loop of the program begins.
After the sweep concludes, the four pre-raw S-parameters are read from the analyzer into memory arrays. The error-corrected (calibrated) S-parameters are calculated and the calibrated data for the S-parameter selected earlier is read into the analyzer and saved to the analyzer’s internal memory. A new sweep is initiated and the loop repeats if there has been no keyboard activity.

Upon exit of the loop, the analyzer is set up to display the active measurement trace. The analyzer’s internal calibration is turned back on and continuous sweep mode is resumed before the program ends.
Example 3: Measurement Data Transfer

There are two methods that can be used to read trace information from the analyzer:

- selectively, using the trace markers
- completely, using the trace-data array

If only specific information (such as a single point on the trace or the result of a marker search) is required, the marker output command can be used to read the information. If all of the trace data is required, see Examples 3B through 3E for examples of the various formats available.

Trace-Data Formats and Transfers

Refer to Table 2-4. This table shows the number of bytes required to transfer a 201-point trace in the different formats. As you will see in the first example (FORM 4), ASCII data is the easiest to transfer, but the most time consuming due to the number of bytes in the trace. If you are using a PC-based controller, a more suitable format would be FORM 5. To use any trace data format other than FORM 4 (ASCII data) requires some care in transferring the data to the computer. Data types must be matched to read the bytes from the analyzer directly in to the variable array. The computer must be told to stop formatting the incoming data and treat it as a binary-data transfer. All of the other data formats also have a four byte header to deal with. The first two bytes are the ASCII characters "\#A" that indicate that a fixed length block transfer follows, and the next two bytes form an integer containing the number of bytes in the block to follow. The header must be read in to separate it from the rest of the block data that is to be mapped into an array. "Array-Data Formats," located earlier in this chapter, discusses the different types of formats and their compositions.

Data may also be transferred from several different locations in the trace-processing chain. These examples will illustrate formatted-data transfers, but other locations in the trace-data processing chains may be accessed. See Figure 1-3.

In this section, an example of each of the data formats will be shown for comparison. In general, FORM 1 (internal binary format) should be used for traces that are not being utilized for data content. Calibration data that is being transferred to a file and back is good example. See Example 3D.

Arrays which will be interpreted or processed within your program should be in FORM 2, 3 or 5, whichever is appropriate for your computer. Example 3C shows how to transfer a trace in these formats.

In Examples 3B and 3C, the frequency counterpart of each data point in the array is also determined. Many applications generate a frequency and magnitude, or a phase array for the test results. Such data may be required for other data processing applications (such as comparing data from other measurements).

In Example 3B, the frequency data is constructed from the frequency span information. Alternatively, it is possible to read the frequencies directly out of the instrument with the OUTPLML command. OUTPLML reports the limit-test results by transmitting the stimulus point tested, a number indicating the limit-test results, and then the upper and lower limits at that stimulus point (if available). The number indicating the limit results is a -1 for no test, 0 for fail, and 1 for pass. If there are no limits available, the analyzer transmits zeros. For this example, we delete the limit test information and keep the stimulus information.

In Example 3C, the limit-test array is read into the controller and used to provide the values directly from the analyzer memory. Reading from the limit-test array is convenient, although it outputs the results in ASCII format (form 4), which may be slow. If there is no other way to obtain the frequency data, this transfer time may be acceptable. Frequency information becomes more difficult to determine when not using the linear sweep mode. Log-frequency
sweeps and list-frequency sweeps have quite different values for each data point. For these special cases, the additional time spent reading out the limit test results is an acceptable solution for obtaining the valid frequency information for each data point in the trace.

Example 3A: Data Transfer Using Markers

Note  This program is stored as EXAMP3A on the “Programming Examples” disk received with the network analyzer.

Markers are the simplest form of trace-data transfer. A marker may be positioned using one of three methods:

- by a frequency location
- by an actual data point location
- by a trace-data value

In the following example, the marker is positioned on the trace’s maximum value. Once positioned on the trace, the trace data at that point can be read into the controller. The marker data is always returned in FORM 4, ASCII format. Each number is sent as a 24-character string. Characters can be digits, signs, or decimal points. All characters should be separated by commas. In the case of markers, three numbers are sent. The display format determines the values of the marker responses. See Table 1-4, “Units as a Function of Display Format.”

When using trace data, it is important to control the network analyzer’s sweep function (and therefore the trace data) from the computer. Using the computer to control the instrument’s sweep insures that the data you read into the controller is in a quiescent or steady state. It also insures that the measurement is complete.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The selected frequency span is swept once.
- The marker is activated and placed on the maximum trace value.
- The three marker values are output to the controller and displayed.
- The instrument is returned to local control and the program ends.
The program is written as follows:

10 ! This program takes a sweep on the analyzer and turns on a marker.
20 ! The marker is positioned on the trace maximum and the marker data
30 ! is output in ASCII format.

280 PRINT
290 PRINT " Compare the active marker block with the received values"
300 !
310 LOCAL @Nwa ! Release HP-IB control
320 END

Running the Program

Run the program. The analyzer is preset and a sweep is taken. Marker 1 is enabled and positioned on the largest value in the trace. The marker is output to the controller and printed on the controller display. The analyzer is returned to local control. Position the marker using the RPG or data-entry keys, and compare the displayed value on the analyzer with the value that was transmitted to the controller.

The three values returned to the controller are:
1. reflection, in dB
2. a non-significant value
3. the stimulus frequency at the maximum point

A non-significant value means that the analyzer returned a value that is meaningless in this data format.

Table 1-4, located in Chapter 1, provides an easy reference for the types of data returned with the various data-format operational modes.
Example 3B: Data Transfer Using FORM 4 (ASCII Transfer)

Note: This program is stored as EXAMP3B on the "Programming Examples" disk received with the network analyzer.

This example shows you how to transfer a trace array from the analyzer using FORM 4, an ASCII data transfer.

*No header is used in FORM 4.

The next most common data transfer is to transfer a trace array from the analyzer. Table 2-4 shows the relationship of the two values-per-point that are transferred to the analyzer. When FORM 4 is used, each number is sent as a 24-character string, each character represented by a digit, sign, or decimal point. Each number is separated from the previous number with a comma. Since there are two numbers-per-point, a 201-point transfer in FORM 4 takes 10,050 bytes. This form is useful only when input-data formatting is difficult with the instrument controller. Refer to Table 2-4 for a comparison with the other formats.

An example of a simple data transfer using FORM 4 (ASCII data transfer) is shown in this program. A fairly common requirement is to create frequency-amplitude data pairs from the trace data. No frequency information is included with the trace data transfer, because the frequency data must be calculated. Relating the data from a linear frequency sweep to frequency can be done by querying the analyzer start frequency, the frequency span, and the number of points in the sweep. Given that information, the frequency of point N in a linear frequency sweep is:

\[ F = \text{Start}_\text{frequency} + (N-1) \times \text{Span}/(\text{Points}-1) \]

Example 3B illustrates this technique. It is a straight-forward solution for linear uniform sweeps. For other sweep types, frequency data is more difficult to construct and may best be read directly from the analyzer’s limit-test array. See Example 3D for an explanation of this technique.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The trace-data array is allocated.
- The trace length is set to 11.
The selected frequency span is swept once.

The FORM 4, ASCII format is set.

The formatted trace is read from the analyzer and displayed.

The frequency increments between the points are calculated.

The marker is activated and placed at the lowest frequency of the analyzer (50 MHz).

The instrument is returned to local control and the program ends.

The program is written as follows:

```
10 ! This program shows an ASCII format trace data transfer using form 4.
20 ! The data is received as a string of ASCII characters, 24 characters
30 ! per data point and transferred into a real array in the controller. The

Running the Program

Run the program and watch the controller console. The analyzer will perform an instrument preset. The program will then print out the data values received from the analyzer. The marker is activated and placed at the left-hand edge of the analyzer's display. Position the marker with the knob and compare the values read with the active marker with the results printed on the controller console. The data points should agree exactly. Keep in mind that no matter how many digits are displayed, the analyzer is specified to measure:

- magnitude to a resolution of 0.001 dB
- phase to a resolution of 0.01 degrees
- group delay to a resolution of 0.01 ps

Changing the display format will change the data sent with the OUTPFORM transfer. See Table 2-4 for a list of the specific data that is provided with each format. The data from OUTPFORM reflects all the post processing such as:

- time domain
- gating
- electrical delay
- trace math
- smoothing
Example 3C: Data Transfer Using Floating-Point Numbers

This program is stored as EXAMP3C on the "Programming Examples" disk received with the network analyzer.

This example program illustrates data transfer using FORM 3 in which data is transmitted in the floating-point formats. FORM 2 is nearly identical except for the IEEE 32-bit format of 4 bytes-per-value. FORM 5 reverses the order of the bytes to conform with the PC conventions for defining a real number.

The block-data formats have a four-byte header. The first two bytes are the ASCII characters "#A" that indicate that a fixed-length block transfer follows, and the next two bytes form an integer containing the number of bytes in the block to follow. The header must be read in so that data order is maintained.

This transfer is more than twice as fast as a FORM 4 transfer. With the FORM 4 transfer, 10,050 bytes are sent (201 points × 2 values-per-point × 24 bytes-per-value). Using FORM 2 to transfer the data, only 1612 bytes are sent (201 points × 2 values-per-point × 4 bytes-per-value). See "Array-Data Formats" in Chapter 1.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The integer variables are defined to contain the header information.
- The number of points in the trace is set to 11.
- The selected frequency span is swept once.
- Data-transfer format 3 is set.
- The headers are read from the trace.
- The array size is calculated and allocated.
- The trace data is read in and printed.
- The marker is activated and placed at the lowest frequency of the analyzer (50 MHz).
- The instrument is returned to local control and the program ends.

The program is written as follows:

10 ! This program shows how to read in a data trace in IEEE 64 bit format. The array header is used to determine the length of the array and to allocate the array size.

Running the Program

Run the program. The computer displays the number of elements and bytes associated with the transfer of the trace, as well as the first 10 data points. Position the marker and examine the data values. Compare the displayed values with the analyzer’s marker values.
Example 3D: Data Transfer Using Frequency-Array Information

Note This program is stored as EXAMP3D on the "Programming Examples" disk received with the network analyzer.

Example 3C was used to read in the trace-data array. Example 3D explains how to use the limit-test array to read the corresponding frequency values for the completed trace array into the controller. The analyzer is set to sweep from 50 MHz to 200 MHz in log-frequency mode with the number of points in the trace set to 11. This makes it very difficult to compute the frequency-point spacing in the trace. The points are equally spaced across the trace, but not equally spaced in relation to frequency (because the frequency span is displayed in a logarithmic scale, as opposed to a linear scale). The limit-test data array may be read from the analyzer to provide the frequency values for each data point. Four values are read for each data point on the analyzer. The test results and limit values are not used in this example. Only the frequency values are used. This technique is an effective method of obtaining the non-linear frequency data from the analyzer display. The test data and frequencies are printed on the controller display and the marker is enabled to allow the operator to examine the actual locations on the analyzer display.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The integer variables for the header information are defined.
- The number of points in the trace is set to 11.
- The frequency span (50 MHz to 200 MHz) is selected.
- The log-frequency sweep is selected.
- The data-transfer format 3 is set.
- The headers are read from the trace.
- The array size is calculated and allocated.
- The trace data is read in.
- The limit-test array is calculated and allocated.
- The limit-line test array is read in.
- The table header is printed.
- The program cycles through the trace values.
- The trace data and frequency are printed.
- The discrete-marker mode is activated.
- The marker is activated and placed at the lowest frequency of the analyzer (50 MHz).
- The instrument is returned to local control and the program ends.
The program is written as follows:

10 ! This program shows how to read in a trace and create the frequency
20 ! value associated with the trace data value. EXAMP3C is used to
30 ! read in the data from the analyzer. The start and stop
40 ! frequencies are set to provide two decades of log range. Log sweep
50 ! is set and the frequency data points are read from the limit test

**Running the Program**

Run the program. Observe the controller display. The corresponding frequency values are shown with the trace-data values. Position the marker and observe the relationship between the frequency values and the point spacing on the trace. Compare the trace-data values on the analyzer with those shown on the controller display.
Example 3E: Data Transfer Using FORM 1 (Internal-Binary Format)

Note

This program is stored as EXAMP3E on the "Programming Examples" disk received with the network analyzer.

FORM 1 is used for rapid I/O transfer of analyzer data. It contains the least number of bytes-per-trace and does not require re-formatting in the analyzer. This format is more difficult to convert into a numeric array in the controller.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The integer variables for the header information are defined.
- The string variable for the header is defined.
- The selected frequency span is swept once.
- The internal-binary format is selected.
- The error-corrected data is output from the analyzer.
- The two data-header characters and the two length bytes are read in.
- The string buffer is allocated for data.
- The trace data is read into the string buffer.
- The analyzer is restored to continuous-sweep mode and queried for command completion.
- The instrument is returned to local control and the program ends.
The program is written as follows:

10 ! This program is an example of a form 1, internal format data
20 ! transfer. The data is stored in a string dimensioned to the
30 ! length of the data being transferred.
40 !
50 ! EXAMP3E

450 ENTER @Nwa;Reply ! Read the 1 when complete
460 !
470 LOCAL @Nwa ! Release HP-IB control
480 END

Running the Program

The analyzer is initialized. The header and the number of bytes in the block transfer are printed on the controller display. Once the transfer is complete, the number of bytes in the data string is printed. Compare the two numbers to be sure that the transfer was completed.
Example 4: Measurement Process Synchronization

![Diagram of measurement process synchronization]

**Figure 2-2. Status Reporting Structure**

**Status Reporting**

The analyzer has a status reporting mechanism, illustrated in Figure 2-2, that provides information about specific analyzer functions and events. The status byte is an 8-bit register with each bit summarizing the state of one aspect of the instrument. For example, the error queue summary bit will always be set if there are any errors in the queue. The value of the status byte can be read with the HP-IB serial poll operation. This command does not automatically put the instrument in remote mode, which gives you access to the analyzer front-panel functions. The status byte can also be read by sending the command OUTP:STAT. Reading the status byte does not affect its value.

The status byte summarizes the error queue, as mentioned before. It also summarizes two event-status registers that monitor specific conditions inside the instrument. The status byte also has a bit (6) that is set when the instrument is issuing a service request over HP-IB.
and a bit (0) that is set in the event-status register when the analyzer has data to send out over HP-IB. See “Error Reporting,” located in Chapter 1, for a discussion of the event-status registers.

**Example 4A: Using the Error Queue**

*Note*  This program is stored as EXAMP4A on the “Programming Examples” disk received with the network analyzer.

The error queue holds up to 20 instrument errors and warnings in the order that they occurred. Each time the analyzer detects an error condition, the analyzer displays a message, and puts the error in the error queue. If there are any errors in the queue, bit 3 of the status byte will be set. The errors can be read from the queue with the OUTPERRO command. OUTPERRO causes the analyzer to transmit the error number and message of the oldest error in the queue.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The error-message string is allocated.
- The analyzer is released from remote control.
- The program begins an endless loop to read the error queue.
- The status byte is read with a serial poll.
- The program tests to see if an error is present in the queue.
- The error-queue bit is set.
- The program requests the content of the error queue.
- The error number and string are read.
- The error messages are printed until there are no more errors in the queue.
- The instrument is returned to local control.
- The controller emits a beep to attract the attention of the operator and resumes searching for errors.
The program is written as follows:

10 ! This program is an example of using the error queue to detect
20 ! errors generated by the analyzer. The status byte is read and
30 ! bit 3 is tested to determine if an error exists. The error queue
40 ! is printed out and emptied.
50 !

330 LOCAL @Nwa ! Release analyzer from remote
340 BEEP 600,.2 ! Beep to attract attention
350 END LOOP ! Repeat error search
360 !
370 END

Running the Program

Run the program. The analyzer goes through the preset cycle. Nothing will happen at first. The program is waiting for an error condition to activate the error queue. To cause an error, press a blank softkey. The message CAUTION: INVALID KEY will appear on the analyzer. The computer will beep and print out two error messages. The first line will be the invalid key error message, and the second line will be the NO ERRORS message. To clear the error queue, you can either loop until the NO ERRORS message is received, or until the bit in the status register is cleared. In this case, we wait until the status bit in the status register is clear. Note that while the program is running, the analyzer remains in the local mode and the front-panel keys may be accessed.

The error queue will hold up to 20 errors until all the errors are read out or the instrument is preset. It is important to clear the error queue whenever errors are detected. Otherwise, old errors may be mistakenly associated with the current instrument state.
Press **System** and then the unlabeled key several times quickly and watch the display. The number of errors observed should correspond to the number of times you pressed the key.

As another example, press **[C]** **CORRECTION ON**. A complete list of error messages and their descriptions can be found in “Error Messages” of the *HP 8753D Network Analyzer User’s Guide*.

The program is in an infinite loop waiting for errors to occur. End the program by pressing **[RESET]** or **[BREAK]** on the controller keyboard.

---

**Note**
Not all messages displayed by the analyzer are put in the error queue: operator prompts and cautions are not included.
Example 4B: Generating Interrupts

Note

This program is stored as EXAMP4B on the "Programming Examples" disk received with the network analyzer.

It is also possible to generate interrupts using the status-reporting mechanism. The status-byte bits can be enabled to generate a service request (SRQ) when set. In turn, the instrument controller can be set up to generate an interrupt on the SRQ and respond to the condition which caused the SRQ.

To generate an SRQ, a bit in the status byte is enabled using the command SREN. A one (1) in a bit position enables that bit in the status byte. Hence, SRE 8 enables an SRQ on bit 3, the check-error queue, since the decimal value 8 equals 00001000 in binary representation. Whenever an error is put into the error queue and bit 3 is set, the SRQ line is asserted, illuminating the (S) indicator in the HP-IB status block on the front panel of the analyzer. The only way to clear the SRQ is to disable bit 3, re-enable bit 3, or read out all the errors from the queue.

A bit in the event-status register can be enabled so that it is summarized by bit 5 of the status byte. If any enabled bit in the event-status register is set, bit 5 of the status byte will also be set. For example ESE 66 enables bits 1 and 6 of the event-status register, since in binary, the decimal number 66 equals 01000110. Hence, whenever active control is requested or a front-panel key is pressed, bit 5 of the status byte will be set. Similarly, ESNEn enables bits in event-status register B so that they will be summarized by bit 2 in the status byte.

To generate an SRQ from an event-status register, enable the desired event-status register bit. Then enable the status byte to generate an SRQ. For instance, ESE 32; SRE 32; enables the syntax-error bit. When the syntax-error bit is set, the summary bit in the status byte will be set. This will, in turn, enable an SRQ on bit 5 of the status byte, the summary bit for the event-status register.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The status registers are cleared.
- The event-status register bit 5 is enabled.
- The status-register bit 5 is enabled.
- The interrupt pointer is enabled and points to a subroutine.
- Two bad commands are set to the analyzer to generate errors.
- The controller reads a serial-poll byte from HP-IB in the event of an interrupt.
- The program tests for an SRQ.
- If the SRQ is not generated by the analyzer, the subroutine stops and displays SRQ FROM OTHER DEVICE.
- If the SRQ was generated by the analyzer, the program reads the status byte and event-status register.
- If bit 5 in the event-status register is set, program prints: SYNTAX ERROR FROM ANALYZER.
- If bit 5 in the event-status register is NOT set, program prints: SYNTAX ERROR BIT NOT SET.
- The SRQ interrupt is re-enabled on the bus.
At the finish, the interrupt is deactivated.

The analyzer is released from remote control and the program ends.

The program is written as follows:

```
10 ! This program is an example of using an SRQ based interrupt to
detect an error condition in the analyzer. In this example, a
30 ! syntax error is generated with an invalid command. The status byte
40 ! is read in and tested. The error queue is read, printed out and
50 ! then cleared.

770 END

Running the Program

Run the program. The computer will preset the analyzer, then pause for a second or two. After pausing, the program sends an invalid command string "STOP 2 GHZ;" to cause a syntax error. This command is intended to be "STOP 2 GHZ;". The computer will display a series of messages from the SRQ-handler routine. The analyzer will display CAUTION: SYNTAX ERROR and the incorrect command, pointing to the first character it did not understand.

The SRQ can be cleared by reading the event-status register and clearing the latched bit, or by clearing the enable registers with CLES. The syntax-error message on the analyzer display can only be cleared by the HP-IB Device Clear (DCL) message or Selected Device Clear (SDC) message. Device Clear is not commonly used because it clears every device on the bus. Selected Device Clear can be used to reset the input and output queue and the registers of a specific instrument on the bus. This will also clear all the interrupt definitions.
Example 4C: Power Meter Calibration

Note  This program is stored as EXAMP4C on the "Programming Examples" disk received with the network analyzer.

For increased accuracy of the analyzer's PORT 1 output power, a power meter calibration is available. This measurement-accuracy enhancement technique is described in "Optimizing Measurement Results" of the HP 8753D Network Analyzer User's Guide. The example described will perform the sample and sweep calibration under HP-IB remote control.

The power meter is usually connected to PORT 1 for the forward measurements. Its address must be set correctly and it must be connected to the HP-IB. The power meter address can be set by pressing: [local] SET ADDRESSES ADDRESS P MTR/HPIB and using the [1] and [4] keys or the numeric key pad to complete the process. The appropriate command must be selected for the model number of power meter being used. Press POWER MTR: [ ] until the model being used is displayed between the brackets.

The correction factors for the power sensor are entered into the analyzer. All of these steps are explained in the "Optimizing Measurement Results" chapter of the HP 8753D Network Analyzer User's Guide.

The number of readings-per-point must also be selected before starting. The number of points directly affects the measurement time of the calibration sequence. The power meter must be triggered and read by the analyzer for each trace point. Typically, two readings-per-point is considered appropriate. More than two readings-per-point could lead to unacceptable processing time.

To control a power meter calibration via HP-IB, the analyzer must be set to pass-control mode. The analyzer must step to the next point in the sweep and read the power present at the power meter sensor. For this operation to take place, the system controller must set up the measurement and then pass control to the analyzer to read each data point in the sweep. After reading the data point from the power meter, the analyzer passes control back to the system controller. The analyzer then sets up to measure the next point and again requests control from the system controller. This process continues until the analyzer signals that the entire sweep has been measured point-by-point.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The number of points in the trace is set.
- The number of readings-per-point is set.
- The frequency span is set.

Note  The frequency span of this example program must be modified in order to correspond to the frequency ranges of the HP 8753D.

- The reference channel is measured.
- The power meter calibration array is allocated.
- The power meter model is chosen.
- The status registers are cleared.
The request-control summary bit is enabled.
- The pass-control mode is enabled.
- A calibration sweep is taken to begin the sequence.
- The status byte is read until control is requested.
- The computer passes control to the analyzer.
- The display is cleared and the analyzer is set to talker/listener mode.
- The HP-IB interface status is read until control is returned.
- The program loops until all the points have been measured.
- The power meter calibration is enabled.
- The calibration data is output to the controller in FORM 4, ASCII format.
- The power meter-calibration factors are read into the controller.
- The analyzer is released from remote control and the program ends.

The program is written as follows:

10 ! This routine does a power meter cal using pass control.
20 ! A measurement cycle takes place on each point of the trace. The
30 ! point is measured by the power meter and the measured value read
40 ! into the analyzer. The command TAKCS; arms this measurement mode.
50 ! The number of measurements is determined by the number of points in
60 ! the trace, the number of readings per point and an extra measurement
70 ! cycle to release the power meter.
80 ! Control is passed to the analyzer, the point is measured and
90 ! the data is transferred to the analyzer. Control is passed back to
100 ! the controller and the cycle begins again. Serial poll is used to
110 ! read the status byte of the analyzer and test the logic.

1070 END

Running the Program

The analyzer is preset and the power meter-calibration routine begins. The analyzer displays the message "WAITING FOR HP-IB CONTROL" when it is requesting control. The system controller display prints "Passing Control" when control is passed to the analyzer. The controller displays "Waiting for request" while the analyzer has control and is reading the power meter.

The interaction of the messages and the movement of the cursor allow observation of the calibration process. Once the calibration is complete, the analyzer displays "POWER METER CAL IS COMPLETE" and the system controller displays "Finished with Power meter Cal".

The power meter-calibration mode (with one sweep of correction data) is enabled and the calibration is switched ON. At the completion of the program, talker/listener mode is restored, the event-status registers are cleared (to halt the status-byte interaction), the power meter correction factors are displayed, the sweep is placed in continuous-sweep mode, the analyzer is released from HP-IB control, and the program ends.
Example 5: Network Analyzer System Setups

Saving and Recalling Instrument States

Note The most efficient option for storing and recalling analyzer states is using the analyzer’s internal registers to save the CAL data. Recalling these registers is the fastest solution to restoring analyzer setups. See “Printing, Plotting, or Saving Measurement Results” in the HP 8753D Network Analyzer User’s Guide for detailed information on the analyzer’s internal storage registers.

In the event that all the registers have been used, the internal disk drive is not used, or if internal memory limitations exist, then these external solutions become viable.

The purpose of this example is to demonstrate several programming options for storing and recalling entire instrument states over HP-IB. The examples describe two different processes for storing and recalling instrument states. The first example accomplishes the task using the learn string. The second example involves reading both the learn string and the calibration arrays out of the analyzer and storing them to disk or storing them in the system controller itself.

Using the learn string is a very rapid way of saving the instrument state, but using direct disk access has the advantage of automatically storing calibrations, cal kits, and data along with the instrument state.

A complete analyzer setup requires sending the learn string and a calibration array to set the analyzer parameters. The CAL array may also be placed in the analyzer, just as if a calibration was performed. By sending both sets of data, the analyzer may be quickly setup for a measurement.

Several different measurements may be required in the course of testing a device. An efficient way of performing multiple measurements is to send both the calibration array and the learn string, and then perform the measurements.

Example 5A: Using the Learn String

Note This program is stored as EXAMP5A on the “Programming Examples” disk received with the network analyzer.

The learn string is a very fast and easy way to read an instrument state. The learn string includes all front-panel settings, the limit table for each channel, and the list-frequency table. It can be read out of the analyzer with the command OUTPLEAS, and input to the analyzer with the command INPULEAS. The example for a FORM 1 transfer could also have been used. However, Example 5A is the simplest solution for reading the learn string from the analyzer.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The string storage is allocated.
- The learn string is requested.
- The string is read without any processing.
- The analyzer is released from remote control.
- The instrument state is changed by the operator.
- The learn string is sent back to the analyzer.
- The analyzer is released from remote control and the program ends.

The program is written as follows:

```
10 ! This program shows how to retrieve a learn string from the analyzer
20 ! into a string array. The state of the analyzer is then changed and the
30 ! learn string re-loaded to return the analyzer to the previous settings.

310 END
```

**Running the Program**

Run the program. When the program stops, change the instrument state and press (ENTER) on the controller. The analyzer will be returned to its original state by using the learn string.
Example 5B: Reading Calibration Data

Note This program is stored as EXAMP5B on the "Programming Examples" disk received with the network analyzer.

This example demonstrates:

- how to read measurement calibration data out of the network analyzer
- how to read it back into the analyzer
- how to determine which calibration is active

The data used to perform measurement-error correction is stored inside the analyzer in one (or more) of twelve calibration-coefficient arrays. Each array is a specific error coefficient, and is stored and transmitted as an error-corrected data array. Each point is a real/imaginary pair, and the number of points in the array is the same as the number of points in the sweep. The five data formats also apply to the transfer of calibration-coefficient arrays. “Printing, Plotting, or Saving Measurement Results” in the HP 8753D Network Analyzer User’s Guide contains information on the storage locations for calibration coefficients and different calibration types.

A computer can read out the error coefficients using the commands OUTPCALCO1, OUTPCALCO2, ... through OUTPCALC12. Each calibration type uses only as many arrays as required, beginning with array 1. Hence, it is necessary to know the type of calibration about to be read out: attempting to read an array not being used in the current calibration causes the "REQUESTED DATA NOT CURRENTLY AVAILABLE" warning.

A computer can also store calibration coefficients in the analyzer. To do this, declare the type of calibration data about to be stored in the analyzer just as if you were about to perform that calibration. Then, instead of calling up different classes, transfer the calibration coefficients using the INPUCALCmn; commands. The variables mn are a data pair appended to the command representing a calibration number from 01 through 12. When all the coefficients are stored in the analyzer, activate the calibration by issuing the mnemonic SAVC; and trigger a sweep on the analyzer.

This example reads the calibration coefficients into a very large array, from which they can be examined, modified, stored, or put back into the instrument. If the data is to be directly stored on to disk, it is usually more efficient to use FORM 1 (analyzer’s internal-binary format), and to store each coefficient array as it is read in.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- A binary path is assigned.
- The system is initialized.
- The calibration types and number of arrays are defined.
- The integer variables for reading the headers are defined.
- The calibration type and number of arrays are read by the controller.
- The output is formatted in FORM 3.
- The number of points in the trace is read.
- The memory is allocated for the calibration arrays.
- Each calibration array is requested from the analyzer.
- Header information is read with a binary I/O path.
The elements from each calibration array are read in.
The next calibration array is requested until all the arrays have been read.
The calibration type is sent to the analyzer.
Each calibration array is sent.
The calibration is activated.
The analyzer is released from remote control and the program ends.

The program is written as follows:

10 ! This program shows how to manipulate calibration data from the analyzer.
20 ! It demonstrates how to read calibration data from the analyzer, and
30 ! how to replace it. The type of calibration active is determined and
40 ! the program reads in the correct number of arrays. The number of points
50 ! in the trace, and in the cal array, is determined and used to dimension
60 ! storage arrays.

Running the Program

Before executing the program, perform a calibration.

The program is able to detect which type of calibration is active. With that information, it predicts how many arrays to read out. When all the arrays have been sent to the computer, the program prompts the user. The operator then turns the calibration OFF or performs a completely different calibration on the analyzer and continues the program. The computer reloads the old calibration. The operator should not preset the analyzer because the instrument settings must be the same as those that were present when the calibration was taken.

Note

The re-transmitted calibration is associated with the current instrument state: the instrument has no way of knowing the original state associated with the calibration data. For this reason, it is recommended that the learn string be used to store the instrument state whenever calibration data is stored. The next example demonstrates how to reload the analyzer state with both the learn string and the calibration arrays.
Example 5C: Saving and Restoring the Analyzer Instrument State

**Note**  
This program is stored as EXAMP5C on the "Programming Examples" disk received with the network analyzer.

**Note**  
The instrument state may also be stored in the analyzer's internal registers. This is the fastest and most efficient method for toggling between instrument states. This example is for use when the analyzer's internal memory is full, or when the are other internal-memory limitations.

This example demonstrates using both the learn string and the calibration arrays to completely re-program the analyzer state. If you were performing two entirely different measurements on a device and wanted to quickly change between instrument states and perform the measurements, this example program is a potential solution.

The example will request the learn string and calibration array from the analyzer and store them in a disk file on the system controller. Once the storage is complete, the operator will be prompted to change the state of the analyzer and then re-load the state that was previously stored in the disk file. Once the file is created on the disk, the state information can be retrieved from the controller and restored on the analyzer.

**Note**  
The disk file can only be created once. Errors will occur if the operator repeatedly tries to re-create the file.

For this example, only a thru calibration will be performed and transferred. This means only one calibration array will be read from the analyzer and written to the disk file with the instrument state. To work with more elaborate calibrations, additional arrays will need to be defined and transferred to the disk file. This is not difficult, but requires some further programming steps which were omitted in the interest of presenting a simple example.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- A binary path is assigned.
- The integers for reading the headers are defined.
- The system is initialized.
- An array is created to hold the learn string.
- The learn string is requested by the controller.
- The number of points in the trace is read.
- The controller allocates an array for the calibration data.
- The calibration data is read into the controller.
- The controller creates and assigns a data file for the calibration array and the learn string.
- The learn string and calibration array are stored in the disk file.
- The operator presses [ENTER] on the controller to read the calibration data back into the analyzer.
- The learn string is read from the disk file and output to the analyzer.
- The calibration array is read in from the disk file and stored in the analyzer.
The analyzer is returned to continuous-sweep mode.

The analyzer is released from remote control and the program ends.

The program is written as follows:

```
10 ! This program reads an instrument state and stores it in a disk file.
20 ! The learn string and CAL array are both read into the controller and
30 ! then transferred to a disk file for storage. The file contents are
40 ! then restored to the analyzer. The analyzer is preset to the default
50 ! settings before the instrument state is transferred back.

740 END

Running the Program

Setup the analyzer and perform a thorough calibration.

Run the program. The program prompts the operator to change the state of the analyzer and then press [Enter] to continue. At this point, the analyzer state is stored on the disk file in the controller. Pressing [Enter] will begin the transfer from the disk file to internal arrays within the controller and then on to the analyzer.

Once completed:

- The original state will be restored.
- The analyzer will be sweeping.
- The analyzer will be calibrated.
- CDR will be displayed on the analyzer’s display.
Example 6: Limit-Line Testing

Using List-Frequency Mode

The analyzer normally takes data points spaced at regular intervals across the overall frequency range of the measurement. For example, for a 2 GHz frequency span using 201 points, data will be taken at intervals of 10 MHz. The list-frequency mode allows the operator to select the specific points, or frequency spacing between points, at which measurements are to be made. This mode of operation allows flexibility in setting up tests that insure device performance in an efficient manner. By only sampling specific points, measurement time is reduced. List-frequency sweeps are also discussed in “Application and Operation Concepts” of the HP 8753D Network Analyzer User’s Guide. These programs emulate operation from the analyzer’s front panel when using list sweeps.

The following two examples illustrate the use of the analyzer’s list-frequency mode to perform arbitrary frequency testing. Example 6A allows the operator to construct a table of list-frequency segments which is then loaded into the analyzer’s list-frequency table. There are a maximum of 30 segments available. Each segment stipulates a start and stop frequency, and the number of data points to be taken over that frequency range. Example 6B lets the operator select a specific segment to “zoom-in.” A single instrument can be programmed to measure several different devices, each with its own frequency range, using a single calibration. When a specific device is connected, the operator selects the appropriate segment for that device.

Note that list-frequency segments can be overlapped, but the total number of points in all the segments must not exceed 1632.

Example 6A: Setting Up a List-Frequency Sweep

Note: This program is stored as EXAMP6A on the “Programming Examples” disk received with the network analyzer.

The purpose of this example is to show how to create a list-frequency table and transmit it to the analyzer.

The command sequence for entering a list-frequency table imitates the key sequence followed when entering a table from the front panel: there is a command for every key-press.

Editing a segment is also the same as the front-panel key sequence, but remember the analyzer automatically reorder each edited segment in order of increasing start frequency.

The list-frequency table is also carried as part of the learn string. While the table cannot be modified as part of the learn string, it can be stored and recalled with very little effort by storing and recalling the learn string. See “Data Processing Chain” in Chapter 1 for details on using learn strings.

This example takes advantage of the computer’s capabilities to simplify:

- creating a list-frequency table
- editing a list-frequency table

The table is entered and completely edited before being transmitted to the analyzer. To simplify the programming task, options such as entering center frequency, frequency span, or step size are not included.

The list-frequency information may be acquired using the limit-test results array. The actual stimulus points are available as the first element in the array.
The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The existing list frequencies are edited and cleared.
- The number of segments to define is read in.
- An array for the list segments is defined.
- The parameters for each segment are requested.
- If the operator wants to edit, the segment parameters are re-entered.
- The new list is sent to the analyzer.
- The analyzer is released from remote control and the program ends.

The program is written as follows:

10 ! This program shows how to enter and edit a list frequency table.
20 ! Any existing table is deleted and a new table is defined and
30 ! edited. This list is then sent to the analyzer. Any number of
40 ! segments or points may be entered. Be sure not to enter more than
50 ! 1632 points or 30 segments.

650 RETURN
660 END

Running the Program

Caution This example program will delete any existing limit lines before entering the new limits. If this is not desired, omit the line(s) that clear the existing limits (in this case, the command CLEL; contained in LINE 190). This program begins by presetting the analyzer. The programmer will have to add the necessary command lines to set the analyzer to the specific operating conditions required for testing. The example program will show the limit lines defined, but the limits will always fail without additional analyzer setup.

The program displays the frequency-list table as it is entered. During editing, the displayed table is updated as each line is edited. The table is not re-ordered. At the completion of editing, the table is entered into the analyzer, and list-frequency mode is switched ON. During editing, pressing [ENTER] leaves an entry at the old value.

If the analyzer display is within the range of the segments entered, then the number of points-per-segment may be observed on the analyzer’s display.

Activate a marker and select the discrete-marker mode to observe the point spacing. Use an exaggerated scale with just a few points to find the list-frequency spacing between points.
Example 6B: Selecting a Single Segment from a Table of Segments

This program is stored as EXAMP6B on the "Programming Examples" disk received with the network analyzer.

This example program demonstrates how to define a single segment as the operating-frequency range of the analyzer from a table of segments stored in the controller. The program assumes that a list-frequency table has already been entered into the analyzer, either manually, or using the program in Example 6A, "Setting Up a List-Frequency Sweep."

The program first loads the list-frequency table into the computer by reading the start and stop frequencies of each segment and the number of points for each segment. The segment's parameters are then displayed on the computer screen, and the operator can choose which segment is to be used by the analyzer. Note that only one segment can be chosen at a time.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The list-frequency segment is edited.
- The largest segment number is set.
- The highest segment number is requested.
- The number of actual segments is read in.
- A list-frequency table is defined and the segments are read in to the controller from the analyzer.
- The operator selects one of the segments of the sweep.
- The controller "zooms-in" and sweeps the defined segment.
- The operator ends the program by entering segment number (5).
- The analyzer returns to sweeping all the segments in the table.
- The activation loop is ended and the program ends.

The program is written as follows:

```
10 ! This program shows how to select a single segment from a list
20 ! frequency sweep and activate it as the sweep. The list frequency
30 ! table is read from the analyzer and displayed on the computer
40 ! screen. The operator is prompted to select a segment and the
50 ! program then activates it. All the segments are activated upon
60 ! completion.

660 RETURN
670 !
680 END
Running the Program

The program will read the parameters for each list-frequency segment from the analyzer, and build a table containing all the segments. The parameters of each segment will be printed on the computer screen. If there are more than 17 segments, the program will pause. Press (RETURN) to see more segments. The maximum number of segments that can be read is 30 (the maximum number of segments the analyzer can hold). Use the computer’s (Page Up) and (Page Down) keys to scroll through the list of segments if there are more than 17.

After all the segments are displayed, the program will prompt the operator for a specific segment to be used. Type in the number of the segment, and the analyzer will then “zoom-in” on that segment. The program will continue looping, allowing continuous selection of different segments. To exit the loop, type (0). This will restore all the segments (with the command ASEG), allowing the analyzer to sweep all of the segments, and the program will terminate.

Using Limit Lines to Perform PASS/FAIL Tests

There are two steps to performing limit testing on the analyzer via HP-IB. First, limit specifications must be defined and loaded into the analyzer. Second, the limits are activated, the device is measured, and its performance to the specified limits is signaled by a pass or fail message on the analyzer’s display.

Example 6C illustrates the first step, setting up limits. Example 6D performs the actual limit testing.
Example 6C: Setting Up Limit Lines

Note This program is stored as EXAMP6C on the "Programming Examples" disk received with the network analyzer.

The purpose of this example is to show how to create a limit-test table and transmit it to the analyzer.

The command sequence for entering a limit-test table imitates the key sequence followed when entering a table from the analyzer's front panel: there is a command for every key-press. Editing a limit line is also the same as the key sequence, but remember that the analyzer automatically re-orders the table in order of increasing start frequency.

The limit-test table is also carried as part of the learn string. While it cannot be modified as part of the learn string, the learn string can be stored and recalled with very little effort. See "Data-Processing Chain" in Chapter 1 for details on using learn strings.

This example takes advantage of the computer's capabilities to simplify creating and editing the table. The table is entered and completely edited before being transmitted to the analyzer. To simplify the programming task, options such as entering offsets are not included.

This example automates the front-panel operation of entering a limit-test table. Front-panel operation and limits are discussed in the "Application and Operation Concepts" in the HP 8753D Network Analyzer User's Guide.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The limit lines are edited and cleared.
- The number of limits is requested.
- The limit table is created.
- The string array of limit types is created.
- The operator is prompted to enter the new limit values.
- The new limit table is sent back to the analyzer.
- The limit line is activated.
- The limit test is activated.
- The analyzer is returned to local control and the program ends.

The program is written as follows:

```
10 ! This program shows how to create a limit table and send it to the analyzer. The operator enters the desired limits when prompted for the stimulus value, upper and lower value and type of limit.
20 ! desired. Once the table is created, the limits are sent to the analyzer and activated.

Running the Program

Caution This example program will delete any existing limit lines before entering
the new limits. If this is not desired, omit the line(s) that clear the existing
limits (in this case, the command "CLEL;" contained in LINE 190). This
program begins by presetting the analyzer. The programmer will have to add
the necessary command lines to set the analyzer to the operating conditions
required for testing. The example program will show the limit lines defined,
but the limits will always fail without additional analyzer setup.

The program displays the limit table as it is entered. During editing, the displayed table is
updated as each line is edited. The table is not reordered. At the completion of editing, the
table is entered into the analyzer, and limit-testing mode switched ON. The analyzer will
rearrange the table in ascending order starting with the lowest start frequency entry. During
editing, simply pressing [ENTER] leaves an entry at the old value.
Example 6D: Performing PASS/FAIL Tests While Tuning

Note
This program is stored as EXAMP6D on the "Programming Examples" disk received with the network analyzer.

The purpose of this example is to demonstrate the use of the limit/search-fail bits in event-status register B, to determine whether a device passes the specified limits. Limits can be entered manually, or using the Example 5A.

The limit/search-fail bits are set and latched when limit testing or a marker search fails. There are four bits, one for each channel for both limit testing and marker search. See Figure 2-5 “Status Reporting Structure” and Table 2-4 “Units as a Function of Display Format” for additional information. Their purpose is to allow the computer to determine whether the test/search executed was successful. They are used in the following sequence:

1. Clear event-status register B.
2. Trigger the limit test or marker search.
3. Check the appropriate fail bit.

When using limit testing, the best way to trigger the limit test is to trigger a single sweep. By the time the single sweep command (SING) finishes, limit testing will have occurred.

Note
If the device is tuned during the sweep, it may be tuned into and then out of limit, causing a limit test to qualify as "passed" when the device is not in fact within the specified limits.

When using marker searches (max, min, target, and widths), outputting marker or bandwidth values automatically triggers any related searches. Therefore, all that is required is to check the fail bit after reading the data.

In this example, several consecutive sweeps must qualify as “passing” in order to insure that the limit-test pass was not extraneous due to the device settling or operator tuning during the sweep. Upon running the program, the number of “passed” sweeps for qualification is entered. For very slow sweeps, a small number of sweeps such as two are appropriate. For relatively fast sweeps, where the device requires time to settle after tuning, as many sweeps as six or more sweeps may be more appropriate.

A limit-test table can be entered over HP-IB. The sequence is very similar to that used in entering a list-frequency table, as shown in Example 5D. The manual (front-panel entry) sequence is closely followed.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The pass counter is initialized on entry.
- The analyzer takes a sweep.
- The event-status register B byte is output and the channel-1 limit is tested.
- If the device fails the first sweep, the operator is prompted to insure it is tuned correctly and the device is measured again.
- If the device passes the first sweep, the operator is prompted not to touch the device as testing continues.
If the device passes the required number of sweeps, the operator is prompted that the device has passed and to connect the next device for testing.

The program initializes the pass counter and begins to measure the new device.

The program is written as follows:

```
10 ! This program demonstrates Pass/Fail tests using limit lines. The
20 ! program uses the latch-on-fail limit bits in event status register
30 ! B to determine if the device performance passes the specified test
40 ! limit lines. It then requires that the device passes for multiple
50 ! consecutive sweeps in order to ensure that the device is static in
60 ! the response and not varying. The operator specifies how many sweeps
70 ! are required to pass the test.

480 INPUT "PRESS RETURN FOR NEXT DEVICE", Dum$
490 Pass=0 ! Initialize pass counter
500 GOTO Measure ! Begin measurement
510 !
520 END

Running the Program

**Note** This program assumes a response calibration (through calibration) or a full 2-port calibration has been performed prior to running the program.

Set up a limit-test table on channel 1 for a specific device either manually, or using the program in Example 5A.

Run the program, and enter the number of passed sweeps desired for qualification. After entering the qualification number, connect the device. When a sweep passes, the computer beeps. When enough consecutive sweeps qualify the device as “passing,” the computer emits a dual-tone beep to attract the attention of the operator, and then prompts for a new device.

To test the program’s pass/fail accuracy, try causing the DUT to fail by loosening the cables connecting the DUT to the analyzer and running the program again.
Example 7: Report Generation

The analyzer has three operating modes with respect to HP-IB. These modes can be changed by accessing softkeys in the [local] menu. System-controller mode is used when no computer is present. This mode allows the analyzer to control the system. The other two modes allow a remote system controller to coordinate certain actions: in talker/listener mode the remote system controller can control the analyzer, as well as coordinate plotting and printing; and in pass-control mode the remote system controller can pass active control to the analyzer so that the analyzer can plot, print, control a power meter, or load/store to disk. The amount of peripheral interaction is the main difference between talker/listener and pass-control mode.

Example 7A1: Operation Using Talker/Listener Mode

Note: This program is stored as EXAMP7A1 on the “Programming Examples” disk received with the network analyzer.

The commands OUTPLOT and OUTPRIN allow talker/listener mode plotting and printing via a one way data path from the analyzer to the plotter or printer. The computer sets up the path by addressing the analyzer to talk, the plotter to listen, and then releasing control of the analyzer in order to transfer the data. The analyzer will then make the plot or print. When it is finished, it asserts the End or Identify (EOI) control line on HP-IB. The controller detects the presence of EOI and re-asserts control of the HP-IB. This example program makes a plot using the talker/listener mode.

Note: One of the attributes of the OUTPLOT command is that the plot can include the current softkey menu. The plotting of the softkeys is enabled with the PSKTON; command and disabled with the PSKTOFF; command.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The selected frequency span is swept once.
- The plot command is sent to the analyzer.
- The analyzer is set to talker mode and the plotter is set to listener mode.
- The plot is spooled to the plotter.
- The analyzer is set to listener mode when the controller detects an EOI from the analyzer.
- The controller puts the analyzer back in continuous-sweep mode.
- The analyzer is returned to local control and the program ends.

The program is written as follows:

```
10 REM This example shows a plot operation under the control of the
20 REM analyzer. The analyzer is commanded to output plot data, the
30 REM plotter is addressed to listen, and the analyzer to talk. The
40 REM controller watches for EOI at the end of the plot sequence and
50 REM then regains control of the HP-IB operations.
60 REM
70 REM EXAMP7A1
80 REM
```

340 END

Running the Program

The analyzer will go into remote, and make the plot. During the plot, the computer will display the message Plotting and waiting for EOI. When the plot is completed, the analyzer asserts the EOI line on the HP-IB. The computer detects this and displays the End of plot message.

If a problem arises with the plotter, such as no pen or paper, the analyzer cannot detect the situation because it only has a one-way path of communication. Hence, the analyzer will attempt to continue plotting until the operator intervenes and aborts the plot by pressing the analyzer’s [local] key.

Pressing [local] will do the following:

■ Aborts the plot.
■ Causes the warning message CAUTION: PLOT ABORTED.
■ Asserts EOI to return control of the bus to the system controller.

Because of possible peripheral malfunctions, it is generally advisable to use pass-control mode, which allows two way communication between the peripherals and the analyzer.
Example 7A2: Controlling Peripherals Using Pass-Control Mode

Note
This program is stored as EXAMP7A2 on the "Programming Examples" disk received with the network analyzer.

If the analyzer is in pass-control mode and it receives a command telling it to plot, print, control a power meter, or store/load to disk, it sets bit 1 in the event-status register to indicate that it requires control of the bus. If the computer then uses the HP-IB pass-control command to pass control to the analyzer, the analyzer will take control of the bus and access the peripheral. When the analyzer no longer requires control, it will pass control back to the computer.

In this example, the pass-control mode is used to allow the network analyzer to dump a screen display to a printer.

Pass-control mode allows the analyzer to control the printer while sending the screen display to be printed. Once the printer-dump operation is complete, the analyzer passes control back to the controller and the controller continues programming the analyzer. The analyzer requests control from the instrument controller and the controller allows the analyzer to take control of the HP-IB and dump the plot. The instrument controller must not interact with the HP-IB while this remote analyzer control is taking place.

Note
The analyzer assumes that the address of the computer is correctly stored in its HP-IB addresses menu under (local) ADDRESS: CONTROLLER. If this address is incorrect, control will not return to the computer. Similarly, if control is passed to the analyzer while it is in talker/listener mode, control will not return to the computer.

Control should not be passed to the analyzer before it has set event-status-register bit 1 making it Request Active Control. If the analyzer receives control before the bit is set, control is passed immediately back to the controller.

When the analyzer becomes the active system controller, it is free to address devices to talk and listen as required. The only functions denied the analyzer are the ability to assert the interface clear line (IFC), and the remote line (REN). These are reserved for the master system controller. As the active system controller, the analyzer can send and receive messages from printers, plotters, and disk drives.

The following is an outline of the program's processing sequence:

- An I/O path is assigned for the analyzer.
- The system is initialized.
- The status registers are cleared.
- Bit 1 of ESR request control is set.
- The ESR interrupt for SRQ is enabled.
- The pass-control mode is enabled.
- The data is dumped to the printer.
- The program loops until the SRQ bit is set.
- The status byte is read with a serial poll.
- The program tests for bit 6, SRQ.
If SRQ is detected, the program tests for pass control (bit 5 of the status byte).

If the analyzer requests control, the system controller gives the analyzer control of the bus.

The program loops and waits for the analyzer to complete the print dump.

The analyzer reads the interface.

If bit 6 is active in the controller, control is returned from the analyzer to the controller.

The status-byte assignments are cleared.

The analyzer returns to continuous-sweep mode.

The analyzer is returned to local control and the program ends.

The program is written as follows:

```
10 ! This example shows a pass-control operation to print the display
20 ! under the analyzer HP-IB control. The controller reads the status
30 ! of the analyzer looking for SRQ to indicate that the analyzer is
40 ! requesting control. Once control is passed to the analyzer, the
50 ! controller monitors the status of its interface registers to detect
60 ! when the interface is again the active controller. The analyzer will
70 ! pass control back to the controller when finished.

550 END

**Running the Program**

The analyzer will briefly flash the message WAITING FOR CONTROL, before actually receiving control and generating the printer output. The computer will display the Printing from analyzer and waiting for control message.

When the printer output is complete, the analyzer passes control back to the address stored as the controller address under the [local] SET ADDRESSES menu. The computer will detect the return of active control and exit the wait loop. The controller will display the message Control returned from analyzer and then release the analyzer from remote control.

<table>
<thead>
<tr>
<th>Note</th>
<th>Because the program waits for the analyzer's request for control, it can be used to respond to front-panel requests as well. Remove the &quot;PRINALL;&quot; command from the program and run the program. Nothing will happen until the operator requests a print, plot, or disk access from the front panel of the analyzer. For example, press [local] Copy and PRINT MONOCHROME.</th>
</tr>
</thead>
</table>
Example 7A3: Printing with the Serial Port

This program is stored as EXAMP7A3 on the "Programming Examples" disk received with the network analyzer.

This program will select the serial port and program the analyzer to copy its display to a printer. There are a number of commands associated with the serial and parallel ports which allow the programmer to configure the output modes, for example the baud rate and the handshake type used by the port and the printer. In this example, the serial port is configured by the program. The interface may also be configured from the analyzer’s front-panel keys by pressing [local] SET ADDRESSES PRINTER PORT. This menu allows manual selection of the serial-interface parameters.

Since the HP-IB port is not being used for the copy operation, programming of the analyzer and measurement operations may continue once the copy operation has been initiated. An internal spooler in the analyzer’s memory provides buffering of the printer operation. In the example which follows, the status byte of the analyzer is checked to determine when the print operation is complete.

- An I/O path is assigned to the analyzer.
- The analyzer is initialized.
- A single sweep is taken and the analyzer is placed in hold mode.
- The status registers are cleared.
- The copy-complete bit is set and enabled.
- The printer operation and communication modes are set.
- The print command is sent.
- The analyzer is released from remote control and placed in continuous-sweep mode.
- The analyzer is polled until the status bit representing copy complete is detected.
- The analyzer is released from remote control and the program ends.
The program is written as follows:

```
10 ! This program shows how to set up and print the display through the
20 ! serial printer port.
30 !
40 ! EXAMP7A3
50 !
60 ASSIGN @Nwa T0 716 ! Assign an I/O path for the analyzer
70 !
80 CLEAR SCREEN

240 !
250 OUTPUT @Nwa;"PRINALL;" ! Print screen
260 !
270 DISP "PRINTING"
280 !
290 ! Set up next measurement over HP-IB
300 OUTPUT @Nwa;"CONT;" ! Restore continuous sweep
310 !
320 ! Measurements can continue but wait for print to finish
330 REPEAT ! Test for bit 2 (4) ESRB
340 Stat=SPOLL(@Nwa)
350 UNTIL BIT(Stat,2) ! Wait for printer to complete
360 !
370 DISP "DONE"
380 LOCAL @Nwa ! Release HP-IB control
390 END
```

**Running the Program**

Run the program. The analyzer is initialized, set to single-sweep mode, and a sweep is taken. The program sets the system up to print the analyzer's display to an HP ThinkJet printer connected to the interface. At this time, the analyzer can continue making measurements as the ThinkJet prints the display. When the analyzer display has finished printing, the controller displays the message: "DONE", the analyzer is released from HP-IB control, and the program ends.
Example 7B: Plotting to a File and Transferring the File Data to a Plotter

Note

This program is stored as EXAMP7B on the "Programming Examples" disk received with the network analyzer.

Another report-generation technique is to transfer the plotter string to a disk file, and retrieve and plot the disk file at another time. Test time is increased when a hardcopy plot occurs during the measurement process. It may be more convenient to plot the data at another site or time. One solution to this problem is to capture the plot data using the controller and store it to a disk file. This disk file may then be read from the controller and the contents transferred to a plotter. This next example shows a method of accomplishing this task.

The analyzer is initialized without presetting the analyzer. The data that is in place on the analyzer is not disturbed by the program operation. A large string is dimensioned to hold the plotter commands as they are received from the analyzer. The length of this string depends upon the complexity of the analyzer’s display. The analyzer is placed in the single-sweep mode and OPCT; SING; is used to make sure that operation is complete before plotting. The plotting begins with the OUTPLOT; command.

The string transfer is ended by the controller detecting the EOI line which the analyzer pulls at the end of the transfer. The string transfer terminates and the plot data is now stored in a string in the analyzer.

These strings contain ASCII characters which represent the plotter commands in HP-GL (Hewlett-Packard Graphics Language). A disk file is created and the string is written into the file containing the display-plot commands.

Once the strings are transferred to the disk file, the file pointer is rewound and the data read out into a string for plotting. The string is sent to the plotter which uses the commands to generate a plot.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned for the analyzer.
- An I/O path is assigned for the plotter.
- The system is initialized.
- The string for plotter commands is defined.
- The frequency span is swept once.
- The plotter output is requested and read into the plot string.
- A plot file is created in the controller.
- The plot string is stored into the disk file.
- The plot string is read from the disk file and sent to the plotter.
- The analyzer returns to continuous-sweep mode.
- The analyzer is returned to local control and the program ends.
The program is written as follows:

10 ! This program shows how to read the plotter output from the analyzer
20 ! and store it in a disk file as an ASCII file. The disk file is then
30 ! read back into the controller and the plot commands sent to a
40 ! plotter to generate the plot of the analyzer display. This allows
50 ! plotting at a different time than data collection.
60 !

440 ENTER @Nwa;Reply ! Read the 1 when complete
450 LOCAL @Nwa ! Release HP-IB control
460 END

Running the Program

The program begins by initializing the analyzer and placing it into single-sweep mode. The plotter commands are captured into strings in the controller. The controller display prompts Plotter output complete. Press RETURN to store on disk. Pressing [RETURN] causes the data to be stored to disk. Once this task is complete, the program prompts once more,
Plot to file is complete. Press Return to plot. After pressing [RETURN] again, the string output is sent to the plotter and the plot begins. Once the plot is complete, the program prompts Plot is complete. End of program. and the analyzer begins sweeping and returns to local control.

Utilizing PC-Graphics Applications Using the Plot File

You can use this Example 7B to generate a plot that can be read into a PC and used in several different graphics generation programs. HP-GL is a commonly recognized graphic format and may be used to transfer information to PC application programs such as CorelDRAW!®, Lotus Freelance® and other graphics packages. By importing the graphics data into these application packages, you can generate reports in many word-processors.

You can then use graphic-data files to generate the following:

- test results documentation
- data sheets from testing results
- archival information for a digital-storage medium

If you would like to create a disk file for graphics processing, modify the previous program to only store the plotter commands to the disk file. Once the file is renamed to include the extension “.hpg,” the PC will have a DOS-format file that can be imported and examined by the graphics package.

Once the HP-GL file is present in the DOS file system, the HP-GL file is imported and examined with the graphics package. The text labels may need to be rescaled, but on the whole, the graphics results are quite usable.

Example 7C: Reading ASCII Disk Files to the Instrument Controller’s Disk File

Note  This program is stored as EXAMP7C on the “Programming Examples” disk received with the network analyzer.

Another way to access the analyzer’s test results is to store the data onto a disk file from the analyzer. This operation generates an ASCII file of the analyzer data in a CITIFILE format. A typical file generated by Example 7C is shown below:

```
CITIFILE A.01.00

```
This data file is stored by the analyzer under remote control or manually from the front panel. See “Printing, Plotting, or Saving Measurement Results” in the HP 8753D Network Analyzer User’s Guide for more details on manual operation. This program performs the same steps that are required to manually store a file from front panel.

This program stores a file in the same manner as an operator would store a file on to the analyzer’s internal disk drive from the front panel.

This example explains the process of storing the data from the analyzer to a file on the internal disk drive. There is also a program to read the data from the file into a data array for further processing or reformatting to another file type. The internal drive will store in the same format that is present on the disk. A new disk may be formatted in either LIF or DOS. For the example, the assumption has been made that the format transformation has already taken place, and there is a file that can be read record by record, from which data can be retrieved.

The goal of this example is to recover an array of stimulus frequency along with the trace-data values. CITIFILES contain the real and imaginary values of each data point. Some further transformation will be required to obtain magnitude values, for example.

The disk file contents for this example are shown above. This file contains more information than will be used in this example. The file is accessed and the records read from the file and printed on the controller display to observe the actual file contents. The file pointer is reset and the records are then read and interpreted for their data contents.

The first six records are skipped for this example. The seventh record contains the stimulus-frequency values and the number of points in the trace. These values are read from the record. The frequency increment, or point spacing, is calculated and used later the frequency-data calculations for a point. Two more records are skipped and the next is the first record representing data values. The data values are read in a loop until the values for the number of points have been recovered from the file. The data values are tabulated and printed out on the controller display.

The following is an outline of the program’s processing sequence:

- An I/O path is assigned to the analyzer.
- The system is initialized.
- A string is dimensioned to hold a file record.
- The analyzer operating state is set.
- The internal drive is selected for storage (only ASCII data is stored).
- A file name is entered and the data stored into it.
- The operator is prompted to move the disk to the controller disk drive.
- The disk file is read and the contents displayed.
- The file pointer is rewound.
- The file contents are converted to trace data.
- The frequency and complex-data pair is displayed for each point.
- The analyzer is restored to continuous-sweep mode.
- The analyzer is returned to local control and the program ends.
The program is written as follows:

10 ! This program shows how to store an ASCII data file in CITIFILE format
20 ! and retrieve the data with the controller. The disk is written in the
30 ! analyzer system and then moved to the controller disk and the data
40 ! accessed.

Running the Program

The analyzer is initialized and the operating range re-defined to an 11-point trace from 100 to 200 MHz. This setup gives a restricted range to be evaluated when the ASCII data file (CITIFILE) is read in from the controller. The operator is prompted for a 5-character filename to use for storing the data. The analyzer is setup for external storage and stores the data file. Once the “pass control/storage/return control” operation is complete, the operator is prompted to place the disk in the controller disk drive and press **RETURN**. The disk is then read and the records contained in the file are printed on the controller display. A prompt appears, **Press return to continue**, which allows viewing of the file contents. Once **RETURN** is pressed, the data records are read and decoded and a table of the stimulus frequency and the data values are printed.
Example 8: Mixer Measurements

The program included in Example 8 is one of several mixer measurements discussed in the “Making Mixer Measurements” chapter of the HP 8753D Network Analyzer User’s Guide.

Example 8A: Comparison of Two Mixers — Group Delay, Amplitude or Phase

Note This program is stored as EXAMP8A on the “Programming Examples” disk received with the network analyzer.

Using this program, you can measure how two mixers compare in terms of group delay, amplitude or phase. Refer to Figure 2-3.

Figure 2-3. Connections: Comparison of Two Mixers — Group Delay, Amplitude or Phase

The following is an outline of the program’s processing sequence:

- I/O paths are assigned for the analyzer and external source.
- The system is initialized.
The system operator is prompted for the LO and IF frequencies.

The external source frequency and power level are adjusted.

The analyzer's IF frequency settings and power level are adjusted.

The frequency offset mode settings are initialized and the mode is activated.

A response calibration is performed.

The system operator is prompted for the type of measurement.

The selected type of measurement is performed and the display is autoscaled.

The analyzer and source are released from remote control and the program ends.

---

Note: When running the program, the following message may appear: "CAUTION: PHASE LOCK CAL FAILED". This message is expected and will disappear once the prompted frequency values are entered.

The program is written as follows:

```
1   ! This program demonstrates swept IF measurement of group delay,
2   ! amplitude tracking or phase tracking of a mixer under test
3   ! relative to a known "calibration mixer". The external source
4   ! (LO) must be prepared to accept SCPI commands.

Running the Program

The analyzer and source are initialized and the operator is queried for the LO frequency, IF center frequency and span. The source frequency and power level are set, and the analyzer frequency settings and power level are adjusted as well. The analyzer frequency offset mode settings are adjusted, the frequency offset mode is turned on, and a response calibration is performed. The operator is queried for the type of measurement, which is then performed, and the program ends.
Limit Line and Data Point Special Functions

The analyzer has special functions in the area of limit testing and in the detection of min/max data points within limit segments. The information in this section will teach you how to use these limit line and data point special functions. The following topics are included:

- Overview
- Constants Used Throughout This Document
- Output Limit Test Pass/Fail Status Per Limit Segment
- Output Pass/Fail Status For All Segments
- Output Minimum and Maximum Point Per Limit Segment
- Output Minimum and Maximum Point For All Segments
- Output Data Per Point
- Output Data Per Range of Points
- Output Limit Pass/Fail by Channel
**Overview**

The limit line and data point special functions are available as remote commands only. Each command is overviewed in Table 2-5.

### Table 2-5. Limit Line and Data Point Special Functions Commands

### OUTPUT TRACE DATA BY SELECTED POINTS

| Last point     | SEL.MAXPT[D]     | 3      | D  | Selects the last point number in the range of points that the OUTPDATR command will report. D can range from 0 to the number of points minus 1. |
| First point    | SEL.MINPT[D]     | 3      | D  | Selects the first point number in the range of points that the OUTPDATR command will report. D can range from 0 to the number of points minus 1. |
| Specify point  | SEL.PT[D]        | 3      | D  | Selects the single point number that the OUTPDATP command will report. D can range from 0 to the number of points minus 1. |
| Data: point    | OUTPDATP         | 1      |     | Outputs a single trace data value indexed by point. (see SEL.PT[D]) |
| Data: range    | OUTPDATR         | 1      |     | Outputs trace data for range of points. (see SEL.MINPT[D], SEL.MAXPT[D]) |

\(^{\dagger}\) For the definition of a limit segment, see “Example Display of Limit Lines.”

\(^{\ddagger}\) Values returned for limit test status are: 1 (PASS), 0 (FAIL), -1 (NO LIMIT)
Example Display of Limit Lines

The features that output data by limit segment are implemented based on the current definition of a limit segment. The actual limit lines formed by the limit table almost never have a 1-for-1 relationship with the segment numbers in the limit edit table. Out of 18 segments in the limit table, you can create 18 limit lines if (a) all limit segments are contiguous and (b) the last segment extends to the stop frequency. Otherwise, terminating a segment requires a single point which means that constructing a limit line requires two entries (segments) of the limit table. Thus you have a minimum of 9 lines available and those lines will not be referenced by sequential segment numbers.

Figure 2-4 is an example of a screen print of limit lines set up on the two instrument channels. The limit line examples shown are of Flat Line, Slope Line and Single Point Limits. See Table 2-6.

![Diagram of limit lines](image)

</table>

* No test limit-segment is created.

Note that if a single point limit is used to terminate slope lines, no test limit-segment is created. (See Figure 2-4: CH1, Seg4.) Also, if a single point limit is used to terminate a flat line, no test limit-segment is created. (See Figure 2-4: CH1, Seg2.) However, if the single point limit used to terminate the flat line limit has different limit values, a single-point test limit-segment is created. (See Figure 2-4: CH2, Seg2.)
Output Results

Table 2-7 shows the output of the OUTPSEGAM test (min/max of all active segments); note that the segments with asterisks (*) from Table 2-6 have no output in Table 2-7.

<td><strong>Status Definition</strong></td>
</tr>
<tr>
<td>-----------------------</td>
</tr>
<tr>
<td>PASS</td>
</tr>
<tr>
<td>FAIL</td>
</tr>
<tr>
<td>NO_LIMIT</td>
</tr>
</tbody>
</table>

Table 2-8 is an interpretation of the Pass/Fail/No Limit status constants. These constants are used to identify the Pass/Fail/No Limit state on the data strings if status is returned.

<table>
<thead>
<tr>
<th>Table 2-9. Min/Max Test Constants</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>String</strong></td>
</tr>
<tr>
<td>------------</td>
</tr>
<tr>
<td>NO_DATA</td>
</tr>
</tbody>
</table>

Table 2-9 is an interpretation of the min/max test constants. If the selected segment has no associated limit, the NO_DATA string is generated, which reports a stimulus value of 0 and a data value of -1000.
Output Limit Test Pass/Fail Status Per Limit Segment

Two commands allow you to query the pass/fail test status on a limit segment basis: (See previous discussion about segment numbers.)

- SELSEG[D] will select the segment.
- OUTPSEGF will return the status of the limit test for that segment: 1 (PASS), 0 (FAIL) or -1 (NO_LIMIT) if no limit exists for the selected segment number. Due to the non-sequential numbering of actual limit line segments on the screen, some segment numbers will have no associated limits and will thus return NO_LIMIT (-1).

Under the following conditions, OUTPSEGF will issue the following errors:

☐ If the limit testing is OFF: “30: Requested Data Not Currently Available.” To clear the error message, turn the limit test ON.

☐ If the limit table is empty: “204: Limit Table Empty” (this is a new message). To clear the error message, enter a limit table.

In both cases, the error is issued and the command responds with -1 (NO_LIMIT).

The argument for SELSEG[D] is limited by the maximum number of segments allowed in the limit table, which is currently 18. The minimum value for the argument is 1. If the user inputs a number that is outside this range, the active entry limits are invoked, causing the analyzer to return the status for limit 18.

Example:

Sending SELSEG3 and OUTPSEGF may return the following:

1 (segment number 3 passed)

Note

The output is ASCII. Currently, the formatting for integer numbers appears to append a trailing space.
Output Pass/Fail Status for All Segments

The HP-IB command OUTPSEGAF will return the number of segments being reported, followed by pairs of data consisting of the segment number and its status. A segment is reported only if it has an associated limit. The output is only valid if limit test is on. See the previous discussion on pass/fail limits per segment for error conditions.

Example:

Sending OUTPSEGAF may return the following:

3
1, 0
3, 1
5, 0

For an explanation of these results, see table Table 2-10.

Note A new Line Feed character [LF] is inserted after the number of segments and after each data pair.

<table>
<thead>
<tr>
<th>SEGMENTS REPORTED</th>
<th>SEGMENT NUMBER</th>

</tr>
<tr>
<td></td>
<td>3</td>
<td>1</td>
<td>PASS</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>0</td>
<td>FAIL</td>
</tr>
</tbody>
</table>

Table 2-10 is an interpretation of the data returned by the command OUTPSEGAF. For clarification, status definition is also included.

Example Program of OUTPSEGAF Using BASIC

The following program is not included on the Programming Examples disk:

10 OUTPUT 716; "outpsegaf;"

20 ENTER 716; Numsegs

30 PRINT "Receiving status for"; Numsegs; "segments."

40 IF Numsegs>0 THEN

50 FOR I=1 TO Numsegs

60 ENTER 716; Segnum, Pf

70 PRINT USING "DD, 2X, 8A"; Segnum, Pf

80 NEXT I
The example program shows how the OUTPSEGAF command can be used to request the number of active segments and their status. Notice that each segment result must use a new enter command as a line feed terminates each segment data result.
Output Minimum and Maximum Point Per Limit Segment

The command "MINMAX"[ON]OFF" toggles a feature which records the minimum and maximum
data points in all active limit segments. Note that limit testing need not be turned on.

The command OUTPSEG will report the min/max data for the segment previously selected
by SELSEG[N]. The data is returned in a comma delimited string with the segment number,
minimum point stimulus, minimum point value, maximum point stimulus and maximum point
value.

Under the following conditions, OUTPSEG will issue the following errors:

- If the min/max testing is OFF: "30: Requested Data Not Currently Available." To clear the
  error message, turn the min/max testing ON.
- If the limit table is empty: "204: Limit Table Empty" (this is a new message). To clear the
  error message, enter a new limit table.

  When the above error conditions occur, there is no data to report, thus no output is
generated.

  If the selected segment has no associated limit, the NO_DATA string is generated, which
reports a stimulus value of 0 and a data value of -1000.

Example:

Sending SELSEG3 and OUTPSEG may return the following:

3, 1.900000000E+09, -9.900000E-01, 2.123456789E+09, 2.123456E+00

For an explanation of these results, see Table 2-11.

Table 2-11. Example Output: OUTPSEG (min/max per segment)

<table>
<thead>
<tr>
<th>SEGMENT</th>
<th>MIN PT STIMULUS (FREQUENCY)</th>
<th>MIN PT VALUE (dB)</th>
<th>MAX PT STIMULUS (FREQUENCY)</th>
<th>MAX PT VALUE (dB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1.9 GHz</td>
<td>-0.99</td>
<td>2.12 GHz</td>
<td>2.12</td>
</tr>
</tbody>
</table>

Table 2-11 is an interpretation of the min/max data returned using the SELSEG[N] and
OUTPSEG commands.

Note: A new Line Feed character [LF] is inserted after the segment number and after
each data pair.
Output Minimum and Maximum Point For All Segments

Three HP-IB commands allow the user to dump the min-or-max or min-and-max values for all active segments:

- **OUTPSEGAM**: outputs min and max data for each active segment.
- **OUTPAMIN**: outputs the min data for each active segment.
- **OUTPAMAX**: outputs the max data for each active segment.

The OUTPSEGAM output consists of:

- The total number of segments being reported.
- The following data for each segment:
  - Segment number
  - Min stimulus
  - Min value
  - Max stimulus
  - Max value

**Example:**

Sending OUTPSEGAM may return the following:

\[
5, \\
1, 1.900000000E+09, -9.9000000E-01, 2.123456789E+09, 2.123456E+00 \\
3, 2.300000000E+09, -10.000000E-01, 2.600000000E+09, 3.100000E+00 \\
5, 3.200000000E+09, -10.000000E-01, 3.400000000E+09, 3.100000E+00 \\
7, 4.300000000E+09, -10.000000E-01, 4.700000000E+09, 3.100000E+00 \\
8, 5.000000000E+09, -10.000000E-01, 5.400000000E+09, 3.100000E+00
\]

For an explanation of these results, see Table 2-12.

**Note**  
A new Line Feed character [LF] is inserted after the segment number and after each data pair.

<table>
<thead>
<tr>

Table 2-12 is an interpretation of the min/max data returned using the OUTPSEGAM command.
Example Program of OUTPSEGAM Using BASIC

The following program is not included on the Programming Examples disk:

```
10 Minmax: !
20 Mm: IMAGE DD,"\",2X,D.DDDE,2X,SD.DDDE,2X,D.DDDE,2X,SD.DDDE
30 PRINT "TESTING: OUTPSEGAM: min/max points for each segment"
40 OUTPUT 716;"mimaxon;"
50 OUTPUT 716;"outpsegam;"
60 ENTER 716;Numsegs
70 PRINT "receiving data for";Numsegs;"segments"
80 FOR I=1 TO Numsegs
90    ENTER 716;Segnum,Minstim,Minval,Maxstim,Maxval
100   PRINT USING Mm; Segnum, Minstim, Minval,Maxstim, Maxval
110 NEXT I
```
Output Data Per Point

The HP-IB command OUTPDAT returns the value of the selected point using FORM4 (ASCII). The point is selected using the SELPT[N] command. This returns the last point if the selected point is out of range. Otherwise, it uses the same format as that used by the marker value command. These formats are as follows:

<table>
<thead>
<tr>
<th>Display Format</th>
<th>Marker Mode</th>
<th>Marker Readout Format</th>

</tr>
</tbody>
</table>

* Value is insignificant, but is included in data transfers.

The commands in the following example are sent while using the format command LOGM.

**Example:**

Sending SELPT5 and OUTPDATP may return the following:

-3.513410E+00, 0.00915E+15 (Note that the second number is insignificant.)
Output Data Per Range of Points

The HP-IB command OUTPDATR returns the value of the selected points using FORM4 (ASCII). This ASCII format requires many data bytes per point for transfer. For a large number of points, it may be faster to make trace data dumps (OUTPDATA) using a binary format. The range of points is selected using the SELMINPT[N] and SELMAXPT[N] commands (select minimum point, select maximum point of desired point range). These commands return the last max point if the selected points are out of range. Only the SELMAXPT will be returned if the selected minimum point is greater than the selected maximum point.

The commands in the following example are sent while using the format command LOGM.

Example:

Sending SELMINPT5, SELMAXPT7 and OUTPDATR may return the following:

\[
\begin{align*}
3.880465E-01, \ 0.000039E-01 \\
1.901648E-01, \ 1.363988E+11 \\
5.57587E-01, \ 1.258655E+30 \quad \text{(Note that the second number is insignificant)}
\end{align*}
\]

For an explanation of these results see Table 2-14.

Note: A new Line Feed character [LF] is inserted after the segment number and after each data pair.

<table>
<thead>
<tr>
<th>POINT</th>
<th>VALUE</th>
<th>VALUE*</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>.3880465</td>
<td>6.000039E-01</td>
</tr>
<tr>
<td>6</td>
<td>.1901648</td>
<td>1.363988E+11</td>
</tr>
<tr>
<td>7</td>
<td>.557587</td>
<td>1.258655E+30</td>
</tr>
</tbody>
</table>

* These values are insignificant.

Table 2-14 is an interpretation of the min/max data per range of points returned using the SELMINPT5, SELMAXPT7 and OUTPDATR commands.
Output Limit Pass/Fail by Channel

The HP-IB commands OUTPLIM1 and OUTPLIM2 output the status of the limit test for channel 1 and channel 2, respectively.

These commands return the values 1 (PASS), 0 (FAIL), or −1 (NO_LIMIT) if limit testing is disabled. Currently, the results of limit testing can be retrieved by reading a bit in the status register.

Example:

Sending OUTPLIM1 or OUTPLIM2 (channel 1 or channel 2) may return the following:

1 (PASS), 0 (FAIL), or if limit test not enabled then −1 (NO_LIMIT).
